LAVINIUM, an ancient city of Latium, founded by Æneas in honour of his wife Lavinia, between Laurentum and Ardea. At first it retained its importance, probably as a religious centre, in opposition to the claims of Alba, but it sunk after the fall of that city. Although on friendly terms, it seems, along with Laurentum, to have retained a certain measure of independence. In the time of Trajan, under the name of Lauro-Lavinium, it united with Laurentum, and flourished for a few years.

L A W.

PART I.—INTRODUCTORY.

Law. I. Law, as the etymology of the words used to denote it in almost all languages shows, is something *laid* down, or established. The word, in its rudimentary sense, denoted such modes of dealing and rules of conduct as, in early times, convenience suggested and usage established among men. Long after these modes and rules obtained a general recognition on account of their convenience, there were no regular means of enforcing them; they were observed partly to avoid trials of strength, and partly because their utility disposed men to combine to enforce them. Contentions, accordingly, frequently arose, both in regard to matters within their provisions and without them. When these disturbed society, its sovereign, or his functionaries, interfered to adjust the claims of the disputants. In the judgment between them a rule already adopted by the good sense of the people was recognised, or a new one was laid down, and would thenceforth be taken for the expression of the sovereign's will on the matter to which it referred,—the people would incline to observe it in their subsequent dealings, and expect the sovereign to follow it on future occasions. By and by, to prevent the necessity of constantly interfering to quell such contentions, the sovereign would prescribe general rules applicable to a variety of cases, and threaten to punish whoever failed to observe them. The name of law would now be given to these with a fuller meaning than when it denominated rules of usage. By a law would now be understood a rule of action, prescribed to and enforced upon the people by their sovereign; and this may be said to be the strict and original sense of a law. Many such laws, however, must have existed, and have lost much of the arbitrariness which their origin was calculated to stamp upon them before the compound idea of law became complete in men's minds.

Significations of the term law: its rudimentary and primary senses. A law, then, in its original and strict sense, is a rule of action contained in a command of a sovereign, addressed to, and enforced upon, his subjects. Four distinct ideas are brought together by this definition:—1, That of a will as the source of the law; 2, That of a command; 3, That of the authority from which it proceeds; and, 4, That of the beings to whom it is given, as capable of obeying or disobeying it. Other two are incidentally involved in it:—1, That of the end for which the law is given; and, 2, That of the uniformity of conduct resulting from obedience to it. When a law is said to be a *rule*, the attributes of permanency and universality are ascribed to it. It is a command addressed to *all*, or to *whole classes*, in the state. It is a standing order of society.

Ideas connoted by its definition in its primary sense. The applicability of the penalties, which the giver of the law has expressed the intention to inflict on those who disobey it, constitutes its proper sanction. The sanction is essential to the law; and it is plain that, in order to its having a sanction, the power of its giver must exceed that of those to whom it is addressed. The nature of the authority essential to giving the character of law to the commands of a superior is not so clear. The most precise idea that can be given of it is, that it is such as that of one who is habitually obeyed from whatever cause. The relation of a parent and child is of the same kind as must subsist between a superior and inferior, in order that the commands of the former may be laws. In that relation obedience is the general rule; the child has so often yielded, it thinks not of resisting. It is through the habit of obedience on the part of the people that, in long-established communities, the sovereign's unquestionable authority makes up for his want of superior

power, which must always reside with the people themselves.

Law. So far of the conception of a law. It is an expression of will, in the form of a command, sanctioned by applicable penalties, proceeding from a competent authority, prescribing to free agents a rule of action for a particular end, and resulting, generally, in a uniform line of conduct on the part of those to whom it is given.

The word law was probably first used as a concrete general term to denote all the laws emanating from a particular source; and in this sense it is still used, as in the phrases, "English law," "Roman law." Thus used, it denotes the expression of the whole will of a sovereign power respecting his subjects, so far as it is capable of being, and intended to be, enforced. By a more comprehensive generalization than the preceding it acquired its general abstract signification, and was brought to denote what is common to all laws, emanating from whatever source. In its definition, at this stage, are connoted all the ideas involved in the concrete from which it has been derived.

It remains briefly to explain the derived senses of the term. In its definition in any of these it will be found that the ideas connoted by its primary definition are involved imperfectly, or (some of them) not at all, or in a fuller or more perfect sense. It will also be found that, when employed in any of its transitive meanings, it is always accompanied by some adjective, or words indicative of the source, subject, or character of the rule which it is used to denominate, and so far expository of the generalization by which its use in that sense has been brought about: of this the phrases, "Natural law," "Revealed law," "The law of Nature," "The law of God," are examples. Law without addition is still law in its primary sense. It is obvious that, in that sense, when set forth in general terms, there is nothing to prevent law existing among any intelligent beings between whom the relation of superior and inferior may be established. Thus, "the revealed law"—the expressed will of God prescribing rules of conduct to man under the sanction of divine punishments—is law without addition wherever it is declared, its definition connoting, at their fullest, all the ideas involved in law. On whatever matters this law is declared, it is a rule superior to all others. The ten commandments, and other rules to be found in Scripture, constitute the revealed law in Christian countries. When the phrase, "The Moral law," is used to denote these commandments, it is of course part of the revealed law. Some, indeed, claim divine authority for the moral law,—meaning thereby a body of doctrine as to conduct, derived from conscience, assumed to be the representative of Deity in the heart of man. If "the Revealed law" is law in its highest perfection, "International law" is law in its rudimentary form. It denotes the rules of the relationships of states established by convenience and usage, but enforced by no regular sanction, and which are observed to avoid war, and because their utility disposes states to combine to enforce them.

So far, it is apparent, the term has not travelled far from its original meaning. The next stage of transition, however, is more remarkable. "The law of Reason," or "the law of Nature," is a rule of conduct established by reason. Its ostensible foundations are a knowledge of human nature and certain first principles, as that men should be just, truthful, and humane; and it consists of such rules as philosophers have thereon founded, and have

Law. declared to be universally binding on men. They call them law, because they are rules, as they say, prescribed by reason, under the sanction of immediate feelings of self-disapprobation and of certain remote disadvantages to those who transgress them, which, indeed, reason cannot inflict as penalties, but which it predicts will certainly follow the transgression of the rules. They thus generalize the term to the extent of admitting into its definition certain ideas, not the same, but akin to those connoted by its original definition. Reason may be more properly said to recommend than to prescribe its rules to man. It has ample authority, but wants power; and, though advice given in the tone of authority comes closely up in idea to command, it is only by courtesy that reason can be said to prescribe rules which it cannot enforce. And though its rules are not without a sort of sanction, yet their giver is neither directly nor indirectly the inflictor of the penalties. Lastly, the rules of reason are not dictated by one will to another; but, whatever force they have, they owe to being approved by the reason of him to whom they are addressed.

Natural laws. By a wider generalization than in the case just discussed, all save one of the ideas connoted in the primary definition came, if not to be excluded from, at least to be allowed to enter only implicitly into, the sense of the term. This is the generalization by which it was brought to denote propositions setting forth uniformities obtaining among natural phenomena. When the term law is used, as in the phrase, "The law of gravitation," to denote such an invariable relation of things as that bodies attract each other by a force proportional to their masses directly, and to the squares of the distances between them inversely, what ideas does it involve in common with the same term used to denote a statute of the realm? *Prima facie*, it is a name given to a statement of fact,—to the formula expressing an invariable relation existing between bodies, involving only the idea of uniformity in common with the concrete from which it was derived. The rationale of this transition is discoverable in the history of science, and the transition itself was less violent than might at first sight appear. Referring the invariable relations of natural phenomena to the Ruler of the universe as the establisher of them, the proposition expressing any one of them, and the fiat by which it was established, are seen to be identical with a change of mood.

Laws in this sense are called natural laws, either ultimate, derivative, or empirical. Ultimate natural laws are those simple uniformities obtaining among phenomena, and arrived at after a sufficient induction; and which cannot be, or as yet have not been, resolved into other and more general uniformities. Such is the law of gravitation. Derivative natural laws depend upon, and are resolvable into, one or more uniformities, which themselves are simple and fundamental. Such is the law of the planetary motions. Empirical laws are derivative natural laws of unknown derivation. Such is the curious numerical relation subsisting between the respective distances of the planets from the sun.

Confusions in the use of the term law. II. The phrases "natural law" and "the law of nature" are perfect equivalents in the sense of science, it not being intended, however, to convey that there is a single simple uniformity to which all natural laws are referable. While their scientific use is thus settled, great confusion exists in their use in writings on law. While some employ them as equivalents, others put them in opposition. By natural laws, some mean those which were observed by men in an imaginary state of existence preceding the establishment of society; while others mean those which, by their constitution, men observe even in society. Some, again, call the "law of reason" "the law of nature;" while others, regarding natural laws as being imposed upon things by the reason of God, and one with the law imposed by reason upon man, give the phrase so wide a meaning as to include under

it both "the law of reason" and natural law in the sense of science.

Law. "To come to the law of nature," says Hooker (*Eccles. Polity*, The law of book i.), "albeit thereby we sometimes mean that manner of nature and working which God has set for each created thing to keep; yet, forasmuch as those things are termed most properly natural agents which keep the law of their kind unwittingly, as the heavens and elements of the world, which 'can do no otherwise than they do;' and forasmuch as are given unto intellectual natures the name of *voluntary agents*, that so we may distinguish them from the other, expedient it will be that we sever the law of nature observed by the one from that which the other is tied unto." And again, in explanation of the nonconformance of voluntary agents to the "law of nature" to which they are tied:—"See we not plainly that the obedience of creatures unto the law of nature is the stay of the whole world? Notwithstanding, with nature it sometimes cometh to pass as with art. Let Phidias have rude and obstinate stuff to carve, though his art be that it should, his work will lack that beauty which otherwise, in fitter matter, it might have had. He that striketh an instrument with skill, may cause, notwithstanding, a very unpleasant sound, if the string whereon he striketh chance to be incapable of harmony. In the matter whereof natural things consist much of it is sometimes such as will by no means yield to receive that impression which were best and most perfect." Here the law of nature is divided into two parts, according to the division of natural subjects into intelligent and unintelligent; and while each of these divisions is separately spoken of as the law of nature relative to its subject, they are jointly so denominated when said to be the stay of the whole world. Montesquieu (*Spirit of Laws*, b. i., c. 1) has fallen into the same confusion in language; and both writers agree in charging a defect upon nature in respect of man's nonobservance of "the law of nature," meaning thereby the law imposed upon him by reason.

The difficulty, however, vanishes if we keep in view the different senses of the term law; and notice how, upon human actions, there may be a superimposition of law upon law in different senses. Natural laws may be predicable of them, and, at the same time, and arising out of their constitutional order, they may partly be determined by law in its primary sense, and partly by rules recommended by reason. From the nature of human beings, which is social, and from the natural conditions of their association, sprung government and laws; from their nature also, which is rational, disposing them to acts of generalization and reflection, government and law became the subjects of criticism which evolved the law of reason. Thus, the institutions of the state and of reason grew organically out of the constitution of human beings and society; and it is only when this is lost sight of that the mind gets bewildered by the apparent antithesis between them and the laws of nature. Keeping this in view, it appears how men, while conforming to their constitutional order, may infringe that established by the state, and, at any time, recommended by reason; and this just that the constitutional order to which the others are subordinate may be preserved. The recommendations of reason sometimes proceed from wrong thinking and false views, and fail because they are related to an unrealizable ideal of human perfection; and, again, because reason's ideal is transitory, ever attending, though by reflection projected in advance of, experience—a light at the ship's bow, and not a beacon to steer by. It is only when reason interrogates nature before admonishing man that its rules can be conformed to.

Before concluding this section, notice must be taken of **Positive law.** the use of the phrase "positive law." It has been employed in different senses by legists and men of science; by many of the former to denote law of human institution

Law.

by many of the latter to signify natural law. It would be convenient, were there no room for ambiguity, to use it here in the sense of the legists; but, as this cannot be done, it is intended to reject the phrase altogether.

The leading divisions of law: first division.

III. The first division of the law of a state is into two portions—the enacted or written, and the unwritten, common, or customary law. The written, or statute law, is the whole expressed will of the supreme power, establishing and regulating the relations of its subjects; and includes all the laws at any time promulgated by the supreme power, so far as not amended or repealed. The common, or customary law, is that which has grown up with popular usages and customs, and taken shape in the decisions of judges. Being unenacted, it falls short of the full idea of law. Civil equity is a part of the law formed from usages and decisions, but differs from the common law, properly so called, sometimes in its subjects, and more frequently in its modes of procedure and relief.

Civil law.

The statute and common law together compose the law of the state—comprising the whole body of rules by which it is constituted and governed. This has sometimes been called its civil law, which, in this sense, comprises an important portion of what is commonly called international law—viz., those express rules which determine the relations of the members of the state to those of other states. The name of civil law is, however, more frequently given to that portion of the whole law which relates to the constitution of the subject's rights of person and property.

Second division.

The second division of the law of a state is into parts corresponding to the social relations which it governs. 1. The *Constitutional Laws* relate to the supreme authority, the legislature, and the higher public functionaries, and determine the most essential privileges of the subjects. Such in Great Britain are, among others, the Magna Charta, the Habeas Corpus, and the Reform Act of 1832. 2. The *Official Laws* relate to the public service, whose different departments, civil, military, naval, and fiscal, they establish and regulate; they secure the public peace, morals, religion, and health, authorize public works, and determine the manner of their execution. 3. The *Civil Laws* determine the subject's rights of person and property; the regulations and pre-requisites by which they are established, and the manner of administering the laws respecting them. 4. The *Criminal Laws* define and prohibit offences against the state and the exercise of public authority; and against the lives, persons, and property of the subjects. They determine the means of preventing such offences, and the administration of the law respecting them. 5. *Municipal, Police, or Local Law*, is only in part a law of the state in the sense of being prescribed by the supreme authority. It includes some general laws relating to the public peace, and special laws relating to the management of local affairs vested in commissions; but chiefly consists of local laws, established on authority delegated by the state,—as bye-laws enacted by burgh magistrates.

Laws create rights and obligations.

All the rules and institutions of the law of a state are, directly or indirectly, limitations and definitions of the powers of action of its subjects. It commands certain actions to be always done under circumstances which it defines; and it forbids others to be done under any circumstances. The powers of action which it assigns to and vests in particular persons are their *rights*. It follows, from the nature of the case, that rights are powers legally vested in persons over their own or others' persons, or over things to obtain services from them,—meaning by a service, whatever tends to gratify a desire. And to rights correspond obligations. The law, in assigning a power to one, necessarily lays all others under the obligation not to interfere with its exercise; and an act in violation of this obligation is a *wrong*. Wrongs, more briefly, are violations of rights.

Corresponding to rights and wrongs are the legal conceptions of right and wrong. Whatever is conformable to law is *right*, and whatever is contrary to it is *wrong*. These Rights and words have other meanings, which, to prevent confusion, wrongs,—must here be indicated. Rights, in the critical doctrine of right and law, are those powers which *ought to be* vested by law in persons conformably to the rule of perfect benevolence; and wrongs are violations of such rights. Whatever is agreeable to the rule of perfect benevolence is *right*, and whatever is contrary to it is *wrong*. It will be seen that rights established by law may differ from those which, according to the critical doctrine, ought to be established; that what is right in law may be wrong according to that doctrine, and *vice versa*.

Law.

IV. The fulness of the idea of law has not been reached The growth of law. by the whole of any system of laws now administered; but in the progress of civilization, the tendency everywhere is towards its realization. Law is, and has always been, in a state of growth and development. History is clear that in the infancy of society men had no idea of regulating their relations on general or uniform principles, and that they knew no rules except such as their natural interconnection established,—a rude approach towards justice between equals; for the rest, the arbitrary rule of power over weakness. In the progress of society, the tendency everywhere has been to widen the dominion of justice and contract that of brute force. In considering this progress, it is to be kept in view that rules of human action are due to the contact and clashing of men with men. The closer men are pressed together by circumstances the brisker is their action on one another, and the more rapid the adjustment of their relationships. The inhabitants of cities soon feel keenly the necessity of rules for their relations, and of combined action for enforcing them. Cities, accordingly, are the centres of all that is denominated by civilization, as the name indicates; they are, *ex facie*, the birthplaces and nurseries of civility, urbanity, politeness. Among rural populations, from the causes which develope rules of conduct operating in a wider sphere with less intensity, and therefore with less rapidity, the progress is naturally slow, and is mainly effected by influences flowing over from the towns. From a similar cause the progress is slow in the society of nations, and is seen to be accelerated as commerce and improved means of communication bring nations more closely together, and increase the number and weight of their common interests.

The causes of the progress and growth of law are partly to be sought for in the earliest stages of society, regarding which there exists no satisfactory information. In an attempt to explicate them, however, valuable assistance may be derived from various sources. Among these are,—1. The descriptions of early societies in various degrees of savagery which have at different times been given by intelligent observers. 2. Observation of what takes place in the intercourse of nations,—nations forming a society which, from its imperfect organization, and attempts to have laws without a proper sanction, and also in having its origin rather in the necessities than inclinations of its members, resembles all communities in their early stages. 3. The history of law itself, in its different branches, revealing its sources and modes of growth. 4. Observation of what takes place in any new society formed in consequence of the necessities of its members. 5. Observation of the development and tendencies of individuals. From the two last might be deduced the natural conditions of human association, and it was the exclusive consideration of these that led to the fiction of a social compact as the basis of civil society.

This fiction proceeded on the hypothesis, which, however, The origin is wholly without foundation, that society was formed by of society. the aggregation of solitary beings. Society obviously commences in the family: the society of parents into which every human being is born, and in which are to be

Law. found the germs of that subordination to, and recognition of authority which are essential to the civil state; the state where the government is patriarchal is indeed the direct prolongation of the family. As the banyan tends to surround itself with a forest of its own offshoots, so the family tends to multiply families around it, till it becomes the centre of a tribe. The feelings of kindred which connect families in tribes tend, though with a feebleness of force, to bind tribes together in nations; and the sentiment of humanity, which is the feeling of kindred refined and diffused, tends, though more feebly still, to unite nations in the great society of mankind. While such is the gradual development, the specialities of the composition of families and of tribes vary, of course, with race, geographical position, climate, and the prevailing religious beliefs.

The bases of law.

Starting from this very general account of the origin of civil society, it is designed (1), briefly to refer the various bases of law to the necessities of human life to which they correspond; and then (2), to indicate the processes by which laws grew up to protect the various civil institutions. The principal bases of law are four in number:—1, Personal safety; 2, Marriage; 3, Property; 4, Government, each of which must receive brief consideration.

1. *Personal safety* is the first condition of the enjoyment of existence, for without it man's life would be miserable. The provisions of nature for securing personal safety are the instinct of self-preservation, resentment, and sympathy; by the last of which men are led to combine to secure their common safety.

2. *Marriage*.—The origin of the institution of marriage is to be found in the instinctive attraction of the sexes. It corresponds to a leading necessity of human life, which would be intolerable without the orderly gratification of the appetites and affections which it affords. Nature's provisions for the perpetuation of the marriage union are twofold:—The causes which produce it continuing to operate for a considerable time tend to prolong it; and, on the birth of children, the co-operation necessary for their preservation develops the domestic affections which tend to maintain it after these causes have ceased to operate. In virtue of these provisions, the rudest savages, it is found, have given a degree of permanency to this union. The necessity of regulating and guarding it must have been early felt; and it is probable that around it laws first began to grow. In some localities the old names for law and marriage are interchangeable. The German word *ehe*, for example, which now means marriage, meant at one stage of the language also, "law" in general; and *ae*, the corresponding word in Anglo-Saxon, signifies simply "law." While the institution of marriage is to be everywhere found, as the necessity of human life to which it corresponds is everywhere felt, marked differences appear in the modes of regulating it adopted in different localities. These are due, in every case, to local peculiarities; as to the proportion of males to females,—depending on race, climate, and popular pursuits; and the degree of civil equality among the people—depending on the manner in which the governing persons acquired and maintain their authority.

3. *Property*.—The institution of property is ultimately referable to the fact of men's wants being such as the earth does not spontaneously satisfy. Were the objects of desire constantly in lavish excess of the demand for them, the idea of property would never have been formed. Whether men's wants were ever so few and simple as that the earth spontaneously supplied them, is more than is known; but it is certain that the condition was very early reached in which the number of human desires, and the difficulty of satisfying them, gave rise to the conception of property in all sorts of objects. The circumstances which give rise to property necessitate the formation of rules for its acquisition and alienation; and owing to the leading realities of social life

being the same everywhere, the same facts are everywhere held to have the qualities of giving rise to property,—viz., pre-occupancy, labour, donation, succession, and contract. The main necessities of life, for example, being procurable only by labour; and there being no motive to labour without security in the enjoyment of its fruits, it is a condition of existence, as well as of social intercourse, that a man shall have the exclusive enjoyment of the fruits of his labour.

4. *Government*.—Government is the condition of security in the enjoyments of marriage and property. Its institution is traceable to different immediate causes in different localities. Those causes only need here be noticed which are of universal operation, viz.,—1. The desire of security. 2. The experience of the advantages of association for mutual protection and aid, acquired in various forms of association for common objects; as for the purposes of the chase and war, or for mutual protection against domestic enemies. 3. The experience of the necessity of subordination to the leadership of one, in order to reaping the full advantages of association. These having produced a disposition towards government, it required only the rise of a leader, pre-eminent for valour or sagacity, or arrogating authority to himself on grounds connected with the prevailing religious beliefs, to compose the fluent elements of society into the solid fabric of the state.

It would be useless to speculate on the anti-governmental condition of men, if it did not throw light on the causes which lead to government. That condition still crops out, ever and anon, in periods of revolution, and in badly governed countries, in efforts of various kinds to attain the security which the governing persons fail to afford. The recent history of California illustrates it. Every man is at first the defender of his own person and property. When outrages become frequent, a sense of insecurity leads men to combine for the common safety. Offenders are at first punished informally, and without moderation. But when the combination for the public safety acquires solidity, there is less fear of outrage and less precipitation in punishment. Accused persons are admitted to trial, and the execution of punishment is open, formal, and deliberate. Lynch law in America indicates one species of combination which, in a rude state of society, preceded the exercise of the judicial and executive functions of government. A less rude form of association to supplement state-action in affording security may be seen in the societies in England for the prosecution of offenders, many going unpunished for the want of public prosecutors.

Sovereignty is long established before the legislative functions of government are exercised. Its first institutions and acts are those necessary for its own security. Its first agency is for putting down disturbances; its next for preventing them. First, it angrily punishes both parties to disturbances; next, it inquires into the grounds of disputes, and punishes those in the wrong. Lastly, it anticipates disputes by prescribing general rules.

Any view of the order of evolution of law would be false that excluded the fact of a simultaneous progress in the regulation of the various social relations; but, so far as we know, the order has been that which, on *à priori* considerations, might be expected. Laws may be said to have first grown round the marriage relation, next round the institution of property; and, lastly, to have referred to the punishment of offences against the person. The right of private vengeance, and the insatiable character of revenge, long prevented the adoption of rules regarding punishments.

The sources whence laws grew up may be said to be six in number:—1, Equity; 2, Decisions; 3, Contracts; 4, Customs; 5, The will of the sovereign power; and, 6, Opinion acting critically on existing laws. As all laws are referable to nature as their ultimate source, so they acquire their full force only by concurrence with the will of the sovereign.

Law.

Law.

From the sovereign's will law springs forth full-armed; from equity, decisions, contracts, customs, it grows up slowly, and organically.

Equity.

1. *The Birth of Law*.—It is impossible to conceive a time when men did not interfere with each other's enjoyments. But as social relations grew in complexity, and the objects of desire multiplied, desires must have more frequently conflicted, and unsocial tendencies increased in number and strength. With unsocial tendencies, however, must have grown up the means of repressing them; otherwise men would not have held together.

When a stronger interfered with a weaker, there was nothing for the latter but to succumb and bide an opportunity of vengeance. In relationships between the stronger and weaker, therefore, the rule was generally the arbitrary will of the stronger. The case was different between equals—resentment directly checking the tendency to interference. When a difference arose between equals, there being no government, or one too weak to interfere, there was nothing for it but to settle the matter amicably, or fight. Hence arose from their intercourse two methods of settling differences—the combat and the reference; the former finally passing into the legal contest, and in many countries becoming the ally of the latter in trial by jury. The combat—at first an off-hand contest, prompted by conflicting desires—was afterwards converted into a formal encounter, and recognised by various nations as a civil means of determining rights. This law of brute force was latterly accepted as an equitable means of settling disputes, from a false view of the dispensation of Providence, and up to a period not very remote, indeed, survived in our own country. Prudence, however, must soon have established among equals a preference in favour of arbitration as a means of settling most questions. The reference would especially be resorted to on minor questions between persons so nearly equal as to make a recourse to force undesirable to them both. On such questions arising, they would first endeavour to come to terms by private discussion; failing in which an amicable settlement would be obtained by a reference to an impartial person of eminence in the community, whose decision, if approved of, would have influence on future cases of a similar description. As the design here is chiefly to trace the spontaneous evolution of law, our remarks will be confined to the case of an amicable settlement by reference to an arbiter; but they will apply, with a slight change, to the decision of disputes by self-constituted umpires, so far as their decision bears on the growth of law.

The disposition of an impartial person judging between equals is equity, which, in other words, is the disposition to act on the best conceptions of right and wrong. Of these the most advanced public opinion, resting on the ripest common experience of what is convenient, is from the first the practical standard; and the desire to act agreeably to this opinion is of the essence of the equitable disposition. Security for the arbiter's endeavouring to conform to this standard lies in his desire of approbation; but, in fact, in order to his decision being final, influencing future cases, and thus (as we shall see) passing a principle into law, it must approve itself to the unprejudiced persons cognisant of it, and therefore proceed, pretty nearly, on conceptions of right and wrong drawn from the common experience. These conceptions are the guides of equity, and interpreters of its maxims; and are generated by experience of, and reflection on, the realities of things, and what is convenient to them. Without attempting an explication of the manner of their development, it may be indicated in a single case. The maxim of equity, "Give every man his own," must be interpreted before being acted upon. The disposition to act on it may be complete, and yet there be different opinions as to what should be done depend-

Law.

ing on conceptions of the requisites to make a thing "a man's own." The conceptions of these requisites depend on the experience which gave rise to the idea of property in things being vested in particular persons as their rights; and this draws back to certain facts which prudence and convenience concur in leading men to hold to be qualified to give rise to property. A man will defend, as his own, the fruits of his labour, the ground which he has pre-occupied, and what has been given to him as a gift. Hence, among equals, labour, pre-occupancy, donation, will at once be recognised as qualified to give titles to property. Experience, then, produces notions of right and wrong, by establishing certain associations between facts and titles to enjoyments. Interpreted by these, the maxim now reads, "Give every man the fruits of his labour; the ground which he has preoccupied; what he has got by gift;" and so on; and it must have been by a generalization from these particular precepts that the maxim was evolved. It is right to give effect to these qualities of facts, and wrong to prevent their operation. So, generally, experience produces associations of legal qualities and facts; and these are modified by reflection. Their trueness to the realities of things will, of course, depend on the fulness of the experience of these realities, and the accuracy of the reflection upon them. The lessons of experience may be misinterpreted by reflection. Experience may demonstrate, for instance, the evils of immoderate revenge, and yet reflection, misled by the idea of proportionality between injuries and punishments, may produce a rude and false conception of what the proportion between them should be, as in the rule "An eye for an eye," "A tooth for a tooth." Before the associations of legal qualities with facts are fixed by law, they are likely to be loose, and different in different minds according to the peculiarities of individual experience; and we are now to consider how they become fixed in the law.

On the reference being made, and the facts founded on by the disputants being laid before the arbiter, his judgment rises into his mind according to the qualities which he associates with the facts. If the dispute respects the property in a thing, he declares it to be his whom the facts favour. Recalling what was said of his disposition, it appears that his judgment, so far as it is what it aims at being, is a verdict of unprejudiced public opinion, and measure of the people's progress in the formation of conceptions of propriety. When, hereafter, it shall be said that equity entered into the rule of a relationship, let it be understood that the rule rested on an equitable judgment, and realized the conception of right respecting the relationship entertained when it was formed.

2. The discussion on the bearing of decisions on law has been anticipated for the principal part, and, for the rest, may best be introduced in showing their bearing on contracts and customs. The origin of law in decisions of arbiters, or of judges interfering to settle disputes, is proved by the fact that the earliest names of law, of right, and of justice, are words signifying decisions or judgments. The progress is easily traceable in the language of the Greeks. *Θέμις* (from *τῆμι*) their old name for law, signified a decision, decree, or rule, laid down in a particular case. Personifying this idea of law, the Greeks regarded *Themis* as a goddess attached to Zeus, who was conceived of as a judge (and not as a law-maker), issuing *θεμύρες* to settle particular disputes. *Δίκη* and *θέμις* at first rarely denoted justice as an abstract conception, but special claims of right; *δίκη*, which came to signify "natural right," is from the same root as *dico*, and at first signified a decision. The other Greek names for law, *λόγος* (*λέω*, to speak), and *νόμος* (*νέμω*, to distribute), point also to decisions as the origin of law. (Grote's *History of Greece*, vol. ii., p. 111.)

3. In proportion to the necessity for arbitration would be the desire to rule relationships by contract; and the desire to

Law.

prevent differences by ruling relationships by contract would be greater the more they tended to give birth to differences. It is on this principle that the order of the evolution of law is to be explained.

In transactions between equals entered into by contract appeared a farther approach to law. What they agreed upon was the rule of their relationship. What was once satisfactorily the rule of a relationship was repeated. If frequently repeated, it became a custom or usage. Transactions not provided for by contract fell to be decided *ex post facto*; to these a rule previously acted upon, if there was such, would probably be applied. Where there was no clear rule that could be held to be implied, or that could be agreed upon *ex post facto*, recourse was had to other means of settling the matter in dispute, as to a reference to an impartial person, whose decision again influenced future cases, and the terms of future contracts. It is thus the terms of decisions and of contracts grow into customs.

It is worth while considering how far equity enters into rules of law derived from contracts whose terms are privately arranged. Where the contractors put themselves into the position of an impartial person, and settle terms from his stand-point, equity directly enters into the terms. The only case for consideration is where their conceptions of right being modelled on their desires, are made to differ from those commonly entertained, and the rule is reached by a process of double position. Here either the rule of the contract is what bystanders approve of, or it is not; only in the former case will it be adopted and passed into custom. Contracts from this source, then, must involve equity to pass into law. That they should often do so, appears from the consideration, that, in advancing to a rule the contractors are forced to recognise equality of advantage as the ideal rule of the contract.

Customs.

4. We have seen how rules of relationships, formed in the intercourse of equals, pass by arbitration and contract into customs. In early times only equals would submit their differences to the decision of neutral persons, or consent to rule their relationships by contract, because only equals had a common interest in obtaining the settlement of their differences by these means. Equity then entered into all decisions and contracts in early times, and thence into the rules of custom derived from them, and into law, so far as it is an organic growth from the constitution and circumstances of a people. A distinction, already hinted at, must here be brought out between customs due to the intercourse of equals and those due to the intercourse of superiors and inferiors. It was said that from the latter arose no principles for imitation by equals in forming relationships between themselves. It may now be said, that the latter class of customs are permissive and not regulating, and are only for consideration here as illustrating the condition of things from which law gradually rescues men. All the customs that shock one's sense of justice and humanity,—the exposition of infants—the powers of a Roman father over his children,—are remnants of the condition anterior to law, and respect acts and relationships not rescued from that condition, because they lay without the sphere of operation of the causes by which law has everywhere been developed. They are proofs of the slowness of men to extend, by sympathy, to others benefits which, by force, they assert for themselves. That sympathy is among the causes which develop law is certain; but it is only by concurrence with a highly stimulated selfishness that it recovers the relations of superiors and inferiors from arbitrary rule. It is owing to this that law has been, almost everywhere, developed in some degree differently with respect to different classes of the same people. When it was first asserted in cities that law ought to be equal for all, the claim was advanced only for the classes of freemen, who were themselves the parties making it; at first

Law.

περιουκοι, peregrini, immigrants, helots, and slaves of every kind, were disallowed equal privileges. Women everywhere, to this day, are without equal rights. One class of our own people reserve the right of being tried by their peers. But it is in the intercourse of nations, who form as yet a rude society, that the truth of the proposition is most noticeable. War is the moderator of the consciences of states. Where success is easy the sense of justice rarely impedes their aggressive tendencies; where it is difficult, their morality shuts them up to non-interference. In Europe, where the states are interested in maintaining the balance of power, an approach to equity is made in the regulation of the relations of states great and small; but outside Europe,—in India, China, Japan, Africa,—the European states practise the morality of superiors, and gratify every desire, however iniquitous, in satisfying which they are not led into conflict with one another. So that the area over which an approach to law has been made in the intercourse of nations is conterminous with that over which the sense of a common interest extends and identifies the security of individual states with that of all. With the widening of that area, and the increasing intensity of that sense, international law will spread and grow. Nowhere is law, local or international, other than that sense, by its direct or indirect operation, constitutes it. How sympathy of itself fails to effect the recovery of the relations of superiors and inferiors from arbitrariness falls not to be explained here. Whoever appreciates what Adam Smith (*Moral Sentiments*, part i., sect. 3) has written of the dependence of sympathy on imagination, will have no difficulty in understanding the failure.

It is in virtue of public opinion, originating in the experience of what is conducive to the common good, and mostly supported by the authority of religion, that before government is fairly established, and exercises its judicial and executive functions, customs acquire for the rules which they embody some degree of the force and generality of law. One of the first institutions of government is an agency to give effect to the rules of custom,—functionaries appointed by the sovereign to act as judges taking the place of self-constituted umpires and arbiters. Custom, when its rules are thus administered and enforced by the sovereign, is the highest rudimentary form of law. "It is surprising," says Mr James Mill, "to what an extent over the surface of the whole globe law has, in all ages, remained in that state of imperfect existence, if, indeed, with any propriety it can be called a state of existence. In every part of Asia, in all ages, law has remained in that state of existence or non-existence. In Europe, where, at a pretty early period, it became the practice to record in writing the proceedings of the judges, the natural propensity of referring to the past as a rule for the present, begat in time a species of obligation of being directed by the examples which had already been set. This created a uniformity and certainty which, however imperfect, afforded something better than the arbitrary proceedings of Asiatic judges. Yet this was a benefit which had a dreadful alloy. A body, not of law, but of decisions, out of which, on each particular occasion, a law for that particular occasion, as out of the crude ore, was to be smelted, hammered, and wire-drawn, was the natural material out of which to manufacture a system of chicane A system of laws so constructed becomes an instrument of conservation of the barbarous customs and ideas of the times in which they were engendered; and infests society with the evils of an age which it has left behind." Of this effect of custom there will be occasion to write hereafter. By a change of view, however, it is possible to admire instead of deploring that provision of nature by which custom is made to preserve the popular experience, and thus to accumulate the materials which the legislator must employ in attempting

Custom, the highest rudimentary form of law.

Law.
The sovereign power.

to perfect the laws of his country. Even under the legislator's superintendence, law is apt to grow up somewhat rankly; and it is well that its growth is so far independent of his care.

5. As civilization advances, and government becomes firmly established, the sovereign's judicial function is exchanged for the legislative. He enacts new laws, sometimes arbitrarily, sometimes on a principle, and amends and repeals old rules; or rears up a homogeneous and systematic body of law out of the mass of popular usages. Thereafter this body receives successive differentiations and accretions as popular habits change with new occupations. When the sovereign perceives that his interests and those of the people are identical, and that the subordination of individual interests to those of the community is the principle on which legislation ought to proceed, he makes laws in greater consistency with one another; seeks to anticipate cases, and to make law popular and effective by giving it publicity and certainty. The consideration, however, of the bearings of sovereignty on the growth of law must be postponed until the action of opinion on law has been farther considered.

Opinion acting critically on existing laws.

6. While in the growth of law custom drew in and hugged the accidents of the soil round the rules of equity, opinion, based on these, but expanding with improving conceptions, tended to loosen and remove them. It was at first wavering and divided; then men of speculative minds, orators, poets, philosophers, and ministers of religion, gave it precision and definite direction by their sentiments and doctrines. They refined the rude juridical notions of early times, and gave rise to the maxims which, by approving themselves to popular experience, established the despotism of opinion which met many necessities for which neither laws, nor the actual power of each individual, could provide. Whoever violated the rules approved of by the people, had to dread their resentment. Weakness became formidable to power by being armed with the sympathies of mankind.

The manner in which opinion grew up with law, beginning to grow with its first germs, but rapidly shooting in advance of them, and thereafter always maintaining itself in the advance, may be traced in the history of morality; and as the action of morality on law is among the chief of the influences determining its development, it is particularly important that their relation should be understood.

The *rational* of the action of opinion on law is, of itself, simple enough. Experience at once generated rules of action and doctrines respecting conduct; and while use and wont, and convenience, preserved the rules, reflection and riper experience changed the doctrines. The new doctrines, on being propagated, produced popular dispositions, or fell in with them, by which they were in turn passed into rules of law, realized and fixed in the rear of advancing opinion.

Law and morality.

The conceptions of right and wrong struck out in the intercourse of equals were the foundations of opinions respecting conduct. As the highest and lowest in society had their co-equals, all partook of instruction in the same principles—in the same school—if in different forms. We have seen that these conceptions rested on associations of legal qualities with facts, induced by experience of the imprudence and inconvenience of preventing these facts operating to vest enjoyments in particular persons. The conceptions of enjoyments, as properly vested in particular persons, are conceptions of *rights*, and the same experience gave birth to these, and to prudential motives to respect *rights*. It thus at once gave birth to morality and law. As these prudential motives, and the rules for the regulation of the desires based on them, which afterwards passed into moral rules, existed from the first only relatively to the realities, however rude, of law, morality was at the first dependent on, if not coincident with, law. The argument, from another

Law.

point of view, of Dr Whewell (*Elements of Morality*, vol. i., pp. 36, 37), on the dependence of morality on law, when carried back to the limit, establishes the same position. Its truth, however, rests not wholly on an abstract argument; it is an historical fact, that it is some time before morality and law are discriminated from one another. Mr Grote points out the fact that in the Homeric poems only the germ of the distinction between morality and law can be detected. In a note (vol. ii., p. 110), he quotes Nägelsbach (*Homeric Theologie Abschn. V.*, p. 23), as giving "a just and well-sustained view of the Homeric ethics," which is to the effect that it is their characteristic stand-point "that the spheres of legal right, morality, and religiosity are not as yet at all disengaged from each other—so that a man, for example, could be just without being godly—but exist together in undeveloped unity." They are only conceived of as distinct when, by the advance of morality, law stands out by itself as a rule distinct from moral and religious duty. This advance is due to the fact of law realizing and fixing conceptions of right in rules of custom; while morality freely changes and amplifies them, by reflection, on a riper experience than gave them birth. On the advance taking place, it arose from the necessity of moral rules receiving their interpretation from legal dispositions that morality divided into two portions,—the one steady, relative to law, and creating a disposition to conform to it; the other vague, and contemplating better or more convenient dispositions of things than those realized by law. It thus became in a twofold sense the auxiliary of law, aiding at once in enforcing and improving it. It is by the reciprocal influence of morality (and other advanced forms of opinion) and law that the stability of the social progress is secured, opinion steadied, and excessive inequalities in the development of the classes of society prevented. While critical morality tends to improve popular conceptions, and thus to change the rules of law (or custom), the latter react on the former. Opinion in a state of fluidity, in the front of experience, is constantly washing the law, in its centre, of the impurities of the soil; but these in turn enter into opinion, and tone and colour it. A most noticeable instance of this is pointed out by Adam Smith in the Influence of Custom on the opinions of Plato and Aristotle regarding the exposition of infants. In the view of this reaction must be noticed the tendency to finality in morals as affecting the progress of law. The temporary effect of assigning absoluteness to moral dogmas is to increase their authority; but the final effect is to disqualify them for carrying on the improvement of law. Critical morality in the relative form, with the greatest happiness on the whole of society for its standard of right, continues to be the auxiliary and guide of law, because it aims at no more than investigating rules, the true lessons of experience, which, on being discovered, the instincts of men compel them to practise. And, in fact, since circumstances and convenience determine law, and law interprets the rules of morality, it is impossible to make them absolute or universal except in point of form. Even the moral rules,—Be just, pure, humane,—which, being drawn from the essential institutions of society, exist in the morality of every country in the same terms, can have no greater generality than the corresponding rules of law. Purity in Turkey is consistent with polygamy, and humanity in America with the institution of slavery.

Reciprocal influence of law on morality and morality on law.

The relation of other forms of advanced opinion to the growth of law is, for a large part, the same as we have above indicated as subsisting between morality and law, the progress effected resulting from the mutual actions of opinion on law, and law on opinion. When the progress has been carried on up to a certain point, the action of advanced opinion becomes more immediate in its effects, taking place on law itself, instead of on popular dispositions. This is when the legislative functions of government

Law. come to be exercised, and the functionaries of the sovereign become the sole administrators of customary rules. The law then lies open to the criticism of persons able to give immediate effect to their views. Judges now venture to change customary rules, modify them to meet new cases as they arise, and extend them to analogous cases; while the sovereign breaks through them and prescribes, and at least appears to enforce, laws wholly new, irrespective of popular faith in their utility. On this stage being reached, it would seem as if the original causes of the growth of law ceased

All law, in the long run, due to the same causes that develop customary law.

Political liberty.

to operate. But, in fact, their action has merely been changed from the direct to the indirect; for it is only by the concurrence of the individual wills of the people that the sovereign possesses his authority; and this concurrence cannot be long maintained except by a line of action on his part conformable to popular dispositions. The changes in law, then, produced by legislative action are not to be regarded as being arbitrary, but as being, in the long run, the effect of the indirect action of the same causes as develop customary law. The truth of this proposition is sufficiently obvious where the sovereignty of the people is asserted, and they possess political liberty. The distribution of political power and authority among the various classes of the people, which is the practical security for good government in which political liberty consists, facilitates their action on the course of legislation. Though, in consideration of the degree to which this security must be relaxed in order to good government, Montesquieu has made political liberty to consist in the opinion of the people that they are free; yet this opinion itself, supposing that there is nothing more, keeps alive a spirit inimical to state action contrary to their interests, and secures the harmony here contended for. But it is immaterial to the proposition what is the character of the political system, or the source of the concurrence on which the sovereign's authority depends.

The argument, on the general case, of M. Comte (*Philos. Positive*, vol. iv., p. 336, *et seq.*), is conclusive, and is briefly as follows:—That the political régime is, in the long run, in conformity with the corresponding state of civilization, arises from the fact, that the disturbances manifest in the one are due to equivalent derangements in the other. The theory that attributes to the legislator the permanent power of infringing this harmony supposes him to be armed with a sufficient authority. But authority, like every other social power, is necessarily constituted by a corresponding assent, spontaneous or deliberate, explicit or implicit, of various individual wills, resolved, from certain preparatory convictions, to concur in a common action, of which it is first the organ and then the regulator. Thus, authority is really derived from concurrence, and not concurrence from authority, setting aside the necessary reaction, so that no great power can arise except from the strongly preponderating dispositions of the society in which it is established; and when there are no strongly preponderating popular dispositions, such social powers as exist are necessarily feeble and languid; and this correspondence is the more irresistible the more extensive the society is. That the reaction of the political system—the effect of political institutions and events—on the general system of civilization, is great, must be admitted; but it must not be exaggerated so as to be placed before the primary action. In a scientific view, it is to the concurrence of the two that the fundamental agreement of the social organism is due. To the same effect writes Savigny, in maintaining such an organic connection between law and the character of the people as subsists between the latter and their language and manners. This connection, he says, is manifested in the progress of the times. “For law, as for language, there is no moment of absolute cessation; it is subject to the same movement and development as every other popular tendency; and this very development remains under the same law of in-

ward necessity as in its earliest stages. Law grows with the growth, and strengthens with the strength of the people, and finally dies away as the nation loses its nationality. The sum, therefore, of this theory is, that all law is originally formed in the manner in which, in ordinary, but not quite correct language, customary law is said to have been formed; that is, it is first developed by custom and popular faith, next by jurisprudence; everywhere, therefore, by internal silently operating powers, not by the arbitrary will of a lawgiver.”

Law.

V. Long after men in civil society had experimentally wrought out codes of local law and morality in a degree supplanting the rule of brute force, the intercourse of states was wholly faithless, lawless, and unfriendly. Whoever was not of a state was its enemy, and, by coming within its confines, exposed himself to be enslaved, and his property to be confiscated. This in times when there were between them no special grounds of quarrel. In war they ravaged and depopulated each other's countries without mercy, massacring alike armed men and helpless women and children, or sparing them only to make them slaves. Such were the relations of states in Greece in the times of its greatest philosophers; and such the principles on which Rome for seven centuries made war on the world. The ancient moralists, homologating the savage traditions of their times, enforced them by precepts. Nor is this to be wondered at, looking to the effect of custom on opinion alluded to in tracing the growth of local law. Every universal result and exercise of brute force the world agrees to hold legitimate: witness the—at one time—universal institution of slavery. Nor is this agreement anywhere broken up, till it becomes the common interest, through the balance of forces, that the rule of force be abandoned. The balance of forces, however produced and maintained, is the first condition of the birth and growth of law. This is especially clear of international law. It originated in the intercourse of states so nearly equal in power as to be formidable to one another, and between whom, in time, grew up the habit of mutual forbearance. They adopted rules of their various relations on the principle of reciprocity, from the mutual convenience of comity and fear of retaliation. These, embodied in mutual contracts, tacit or express, passed into customs, and were supported, in time, by public opinion amongst nations, resting on the sense of their utility, and the respect for usage. Then this opinion tended to cause the principles of these rules to be applied to the relations of the great and small states; while, concurrently, the mutual jealousies of the great powers tended to widen the area of the common interest, by, in effect, producing a balance of forces between themselves and the less. These principles, being thus diffused, were next made more just and humane, by circumstances which added new common interests to those which the fear of their respective forces, and the perception of the advantages of comity, at first created between states. Among these were the institution of the order of knighthood; the crusades, which united men of many nations in a common action; and chiefly the Romish Church, whose ministers spread over Europe, imbued with the spirit of Roman justice, and sustained by the authority of the pontiffs, tempered the rude disorders of the European family. Then criticism, to which Grotius first gave shape, applying the principles of local justice to the relations of states, helped on the cause of humanity by giving definite direction to the sentiments of the leading minds in various nations, and by, finally, through a succession of teachers, transfusing the better classes of all societies with enlightened views of the duties of nations. But there was another developing cause. The relations of nations were, from the first, affected by the experience of the advantages of commercial intercourse. It is to commerce mainly that we owe the steady increase of the respect to humanity, perceptible

Growth of international law.

Law.

in their intercourse in modern times. By bringing men of various nations face to face, it destroys their local prejudices and antipathies, and while widening their sympathies, it directs them by manifest and sensible interests. Its effects, as a developing cause of international law, have already been so powerful, that an augury of what they may hereafter be, though reasonable, would to most appear fanciful. It is rapidly assimilating the mercantile codes of all the nations in the world, and stripping war of its ugliest features one by one: it is daily making clearer the demonstration, that the interests of nations press them from all sides not to go to war at all, and is thereby undermining the military system. That it will henceforth still more powerfully and rapidly conduce to the harmonious adjustment of international relations, is guaranteed by the steady progress of nations in the industrial arts, and by the inventions that, facilitating their inter-communication, increase its advantages. Wherever a nation has a market, it has an interest that order and prosperity should there prevail. As the subjects of various nations are brought into close and constant intercourse, as the number and weight of their common interests are increased, and as, through the press, their literatures are freely interchanged, they will more and more nearly approach towards sameness of views and sentiments; and be led by that instinct which impels men everywhere to what is advantageous, to concur in desiring that disputes between nations should be adjusted on the principles of equity. The more just and definite rules of international law become, the more obvious will be the advantage of observing them and the mischievousness of war, and it will be seen that the alternative should be dreadful to justify the resort to so clumsy, ineffectual, and horrible an expedient. Public opinion in the various states, resting on the manifest utility and justice of observing the equal rules of international law, will then bind down governments to respect them; while, being everywhere guided by the same leading ideas and principles, it will be distinctly pronounced, and secure a preponderance of sympathy and active assistance from nations to any state whose rights are violated.

While such are the principal developing causes of international law, the inequalities of development of the various nations composing the society of mankind, the varieties of their forms of government, and the mutual jealousies of the governing persons in societies of different constitutions, are among the principal of the causes which have retarded it. But in the growth of international, as of local law, the principles of human nature are seen steadily operating towards the just and harmonious settlement of the relations of men. Hereafter, as hitherto, its progress must be worked out experimentally; and that it will be continued is insured in the great society of mankind, as the progress of civil law is insured within the smaller compass of individual states, by the concurrence of the desires of individuals for happiness, and the common experience that the largest measure of durable good is obtainable only in the way of justice. It is in the view of this security that the scientific truth of the faith, that "all things work together for good" is perceived; for it guarantees that in the long run all might must perish that are exercised prejudicially to the interests of mankind.

Popular tendencies related to law.

VI. In the view of law being everywhere, in the long run, the result of the habitual sentiments of the people, it remains briefly to notice the principal popular tendencies that affect its progress. A tendency, that has almost everywhere been influential, is to conceive one's self out of society in what is called "the state of nature;" and, with the feelings and ideas of society, to consider the faculties of action one would then have. From this sprung the popular conceptions of "natural rights," which, favouring strong desires, and being easily (if vaguely) formed, have powerfully affected politi-

cal systems; to an extent beneficially, by balancing the tendency of sovereigns to arbitrary rule; to an extent also injuriously, by throwing society, in moments of heat, into confusion. The desire of liberty from legal restraints, one of its manifestations, deserves consideration, because its strength depends on errors that may readily be exposed.

Law.
Law and liberty.

"Natural liberty," or the liberty a man would have in the "state of nature," as opposed to what he has in society, is unintelligible in so far as the "state of nature" of man is society. But the idea is, that it is the liberty a man would have in the solitary state, or in a society without laws or government. It appears at first as if a man by relinquishing either of these for a governed society lost a portion of his liberty. But if liberty be defined to be greater or less according to the number of ways in which a man may exercise all his faculties, the number of objects on which he may exercise them, and the extent to which they may be exercised, it is greater in a governed society than in either of the states supposed. However great may be a man's liberty of action in these, he wants, as has well been said, the materials for it. Many of his noblest faculties are exercisable only in a governed society in which others are developed to a degree of activity unattainable in the so-called state of nature. Government and laws subordinating individual to public interests, and prescribing the modes and limits of social activities, establish order and security—the guarantees of human happiness; and while, in a sense, abridging men's liberties, so increase the materials on which the faculties left with them may be exercised as on the whole greatly to enlarge their freedom in the truest sense. The definition of civil liberty which places it in the freedom from legal obligation left, or granted, by the supreme power to its subjects, opens the way to the desire of "natural liberty" as the perfection of freedom. Its true definition destroys that desire. Civil liberty is analogous to what natural

liberty really is. As this consists of freedom of action, uncontrolled save by the wise laws and dispositions of nature by which the harmony and welfare of the world are secured; so that consists in freedom of action, uncontrolled save by such wise and benevolent laws as are necessary for the harmony and welfare of the state. This definition agrees substantially with that given by Sir James Mackintosh (*The Theory of the Laws of Nature and Nations*), when he places liberty in security against wrong. It turns round the tendency from which aspirations after savagery arise, and makes it conduce to the perfection of law and government. The desire for equal laws must here be briefly noticed, from its having acted healthfully on systems of laws. It grew up with the conception of law as designed to secure the public good, and is to be distinguished from the sentimental longing for an equal distribution of the objects of desire among the members of society. It demands security to all in the enjoyment of the fruits of their industry, and that none shall be laid under any obligation with respect to another under which the latter is not put equally with respect to him. The obstacles to the realization of equal laws are,—1, The necessity for government, which requires that the multitude shall always be subordinated to their rulers; and, 2, The selfishness of the governing classes. But supposing laws equalized up to the point consistent with government, they might still fall short of the character which law should have according to the latest conception of it. According to this it is an active force, restricting and directing the various social activities, so as, though in small part, beneficially to determine the character of the social progress. So long as law is determined solely by present convenience, it may fail of securing what is conceived to be its proper end—the permanent welfare of society.

Civil liberty.

Equal laws.

The latest conception of law.

Defects incidental to law from

VII. Preparatory to the inquiry how this latest conception of law is to be realized, it will be well briefly to exhibit the defects incidental to law from its modes of growth, to see of growth.

Legisla-
tion.

what is the knowledge necessary for their rectification. Law branches out in different directions corresponding to its different sources—common law to popular customs—statute law (immediately) to the will of the sovereign—civil equity to certain defects of statute and common law, which it partly rectifies. The first defects, then, to be noticed are four,—1. Defect of consistency between the principles in its different branches. 2. Defect of cognoscibility due to their number, and their being mostly welded into cases, and the difficulties of ascertaining which of them apply to new cases that occur. 3. Defect of equity. That there should be positive defects of equity in the rules of statute and common law, looking to their later stages, is plain enough, considering how often the sovereign's immediate interests conflict with those of the people, and the limits within which authority may be abused without exciting a corrective popular reaction, and how often circumstances warp the judgments of the most conscientious judges. 4. Defects due to its tenacity in carrying forward into one age the imperfect modes of dealing, and forms of expression peculiar to another. These four everywhere tend to work out their own rectification, by producing obvious intricacy and confusion in the administration of justice, and inconvenience and positive injustice in the regulation of relationships. Accepting its rules as having been equitable when formed, it remains to point out their possible defects as discovered in the progress of experience and opinion. These are two, the one due to over-generality or over-particularity in the definitions of the relationships of which they are the rules; the other due to errors in the guiding conceptions of equity at the date of their formation. Instances of the first defect are to be found in plenty in decisions of courts of equity. The "appeal to God," as a means of testing a suspected person, resting on a misconception of the method of the divine government, is an instance of the second. On the belief that the operation of natural laws was always suspended or altered to shield innocence or detect guilt, the test was reasonable, and rules of evidence applying it equitable. Their unreasonableness was only discovered on the falsity of that belief being ex-

posed. A third defect, akin to this, is due to defect of prevision—a short-sighted policy forming rules that soon work injuriously.

Legisla-
tion.

It appears, then, that, so far as concerns law related to justice, the knowledge necessary to cure its defects must include,—1, Correct conceptions of the general cases to be provided for, from which the cases to be exempted from the general rules will at once appear; 2, Correct conceptions of the natural relations of persons and things and their tendencies to change. These demonstrate what the associations between facts and rights, and what rights themselves ought to be, and, had they existed, would have prevented the barbarous laws of evidence above alluded to. The knowledge necessary for the perfection of law related to the determination of the phenomena of society, remains to be treated of in the next part of this article. It will be found to include that necessary for the rectification of law related to justice. "In everything that relates to practice," says Lord Bacon, "we must make up our account as to what is in our power, and what not. For, in the former, alteration is allowed, but, in the latter, application merely. The husbandman hath no power over either the nature of the soil or the weather; nor the physician over the natural frame and constitution of the patient or the variety of accidents. But in the cultivation of the mind, and the healing of its disorders, three things come under consideration—the different characters of disposition, the ailments, and the remedies: as also in the treatment of bodily diseases, these three things are brought under our notice—the habit or constitution of the patient, the disease, and the cure. But of these three, the last only is in our power, not so the two first. But we must make no less careful inquiry into those matters which are beyond our power than into those which are within it. For a distinct and accurate knowledge of them must form the basis of a doctrine respecting the remedies, in order that these may be applied more skilfully and successfully." The remarks here made as to the body and mind of a man, and their treatment, apply directly to the frame and constitution of society, and to legislative action upon it.

PART II.—LEGISLATION.

I. It has been ascertained from the study of the growth of law, that, in the long run, both the laws and political system of a people are reflexes of their habitual sentiments, and tend to change as these do. It follows that a scientific knowledge of the tendencies of human nature and society is the only safe basis of legislative action.

The test of
laws.

The assumption, in every speculation on laws, must be, that they ought so to govern men as to secure the greatest good, on the whole, of society. The test of the goodness of laws is their fitness to secure this good. But of this there can be no test, if the phenomena of society are not subject to natural laws. Whether they are, depends on whether the law of causality applies to human actions; for if it does, social phenomena are certainly subject to natural laws, because they wholly result from the concurrence of the actions of individual men.

Universal experience favours the conclusion that the law of causality applies to human actions. 1. If it did not apply, there could neither be universal principles as to the formation of character, nor could we have the idea of character. But we have that idea, and constantly assume that it is possible to foretell the conduct of one whose character and exact situation are known. 2. In threatening punishments to counteract the motives to offences, the assumption is, that between motives, volitions, and actions there exists the relation of cause and effect. 3. Every one is conscious of the force of circumstantial evidence. Evidence of this sort, in courts of justice, consists usually of two parts,—(1.) Evidence that the accused had a sufficient motive to commit the

offence charged on him; (2.) Evidence that he did commit it. The force of the first part is due to the universal conviction that no one does anything without a motive, and that when a man has a motive he acts upon it, unless it be counteracted. The links of the circumstances which make up the second part are supplied by our conviction that certain actions must have followed the mediate actions indicative of purposes that enter into the circumstances. 4. Whoever has to influence another calculates, from his knowledge of the person's character, what inducements are most likely to weigh with him. He appeals "to the avarice of the miser, the honour of the gentleman, the probity of the man of virtue;" and so confesses his practical belief that "motives determine the will as necessarily as acids act upon alkalis" (Abercromby's *Intellectual Powers*). 5. Spontaneous actions are not separated from, but stand in the front of, the general class: they are due either to direct physical causes, or to dispositions of mind towards certain volitions, originating in deliberations at first consciously preceding them, but at length dispensed with as leading to known conclusions. Whatever is true of actions generally, therefore, is true of spontaneous actions.

That the law of causality applies to human actions may be held, then, to be a truth established by universal experience. It is, in fact, "as palpable and universal as that bodies have weight." It follows that the phenomena of society, which result from the concurrence of the actions of individuals, must be ruled by natural laws derived from those of individual life. It is therefore possible, speaking

Legisla-
tion.

apart from difficulties due to the complexity of social phenomena, for the legislator to obtain scientific guidance in acting on society.

To show how the knowledge which is to yield this guidance is to be obtained, we must briefly inquire into the sciences of human nature and of society. Whoever desires fuller information on these sciences should study the admirable essay of Mr J. S. Mill on the "Logic of the Moral Sciences," *Logic*, vol. ii.; and M. Comte's *Philos. Positive*.

The science
of human
nature.

The science of human nature, as it must be constructed for practical purposes, aims at investigating the laws according to which circumstances affect character and conduct. Owing to the diversities of individual experience, and the fact that every event which happens to a man affects, in some mode or degree, his subsequent mental history, it would be unreasonable to expect that the generalizations men make respecting the feelings or actions of mankind, without reference to the causes which determine them, should be anything but approximate. They are, in fact, of the nature of empirical laws; and unless we have resolved them into the laws of the causes upon which they depend, and ascertained that those causes extend to the cases which we have in view, no reliance can be placed on inferences from them to those cases. The saying, that the old are cautious, is not a scientific truth, but an approximate generalization only; the scientific truth is, that contact with difficulty and danger *tends* to make men cautious. This causal law at once explains the saying, and gives us the limiting principle of our reliance on it. The investigation of such causal laws is the object of the science of human nature. "The science of human nature," says Mr J. S. Mill, "may be said to exist in proportion as those approximate truths which compose a practical knowledge of mankind can be exhibited as corollaries from the universal laws of human nature on which they rest, whereby the proper limits of those approximate truths would be shown, and we should be enabled to deduce others from any new state of circumstances in anticipation of specific experience. . . . Men do not all feel and act alike in the same circumstances; but it is possible to determine what makes one man, in a given position, feel and act in one way, another in another; how any given mode of feeling and conduct, compatible with the general laws (physical and mental) of human nature, has been or may be formed. In other words, mankind have not one universal character, but there exist universal laws of the formation of character. And since it is by these laws, combined with the facts of each particular case, that the whole of the phenomena of human action and feeling are produced, it is upon these that every rational attempt to construct the science of human nature in the concrete, and for practical purposes, must proceed" (*Logic of the Moral Sciences*). The nature of these causal or "ethological" laws, as they have been called by Mr Mill, will now be understood. They must be deduced from the general laws of mind, experimentally investigated by psychology, by supposing sets of circumstances, and then considering what, according to the laws of mind, will be the influence of those circumstances on the formation of character.

The science
of society.

The science of society investigates the laws by which, in the first instance, social phenomena are harmonized, and, in the next, by which they tend to change. Hence its division into two sciences (Social Statics and Social Dynamics), kept distinct for the sake of convenience, but really parts of one, and corresponding to two aspects of the same theory. Social Statics considers the interconnection of the parts of society, and the laws by which they are harmonized; Social Dynamics considers the tendencies of social phenomena to change, and investigates the laws by which one state of society tends to generate another, and by which social effects react on their causes, and determine the nature of the social progress.

Legisla-
tion.

As the causes of social phenomena arise from the composition of the causes of individual phenomena, their laws are derivative from those of psychology and ethology. Hence, however sociological laws may be investigated, it is in their agreement with the laws of psychology and ethology that their verification must be looked for.

The investigation of sociological laws may be conducted on two methods, separately and conjunctly:—1. By deducing social laws from the general laws of mind, and verifying them by deductions from history. 2. By deducing social laws from history, and verifying them by the general laws of mind. M. Comte is of opinion, that the latter method is the only one strictly applicable to sociology. Mr Mill, in assigning importance to the former, admits that a social science formed on that method would be a science of tendencies, and not of positive predictions. "We may be able," he says, "to conclude from the laws of human nature applied to the circumstances of a given state of society, that a particular cause will operate in a certain manner, unless counteracted; but we can never be assured to what extent or amount it will so operate, or affirm with certainty, that it will not be counteracted; because we can seldom know, even approximately, all the agencies which may exist with it, and still less calculate the collective result of so many combined elements. The remark, however, must here be once more repeated, that knowledge insufficient for prediction may be most valuable for guidance. It is not necessary, for the wise conduct of the affairs of society, no more than of any man's private concerns, that we should be able to foresee infallibly the results of what we do. We must seek our objects by means which may, perhaps, be defeated, and take precautions against dangers which possibly may never be realized. The aim of practical politics is to surround the society which is under our superintendence with the greatest possible number of circumstances of which the tendencies are beneficial, and to remove and counteract, as far as practicable, those of which the tendencies are injurious. A knowledge of the tendencies only, though without the power of actually predicting their conjunct result, gives us, to a certain extent, this power." M. Comte, regarding the social science as essentially consisting of generalizations from history, verified by deductions from the laws of human nature, seeks to construct it as a science, not of tendencies, but of positive predictions. If the guidance promised by Mr Mill falls short of the scientific prevision promised by M. Comte, it can be much more easily obtained.

How social
laws are to
be investi-
gated and
verified.

The leading idea of social science, as conceived by M. Comte, is, that society must be regarded as a whole, and singular social facts as strictly inseparable from the whole. There is no doubt that this is the scientific conception of society; but the main difficulties of perfecting social science are connected with this conception. M. Comte is, however, of opinion, that once the leading ideas of the science have been seized, every observation of human nature, and impression from the events of life, will become of value as a sociological indication in aid of the historical method of investigating social laws. He thinks that when men come to make observations on society, with the social theory to guide them to what to observe, the facility afforded by the mutual relation of its various aspects will, in part, compensate for the difficulty caused by that mutual connection,—the inseparableness of the parts from the whole, while rendering observation more difficult, thus providing more means for its prosecution. Mr Mill, however, in anticipation of the arrival of the period when the science will reap the advantages of observations thus conducted, proposes to create several sub-departments of sociological inquiry, and thus to facilitate observation by confining it. The conclusions arrived at in these independent departments must, of course, be less exact, and afford less safe guidance than those of

Legisla-
tion.

the general science. But, as Mr Mill observes, the exactness of science must give place to practical convenience and utility in the science of society, as in astronomy; and there appears to be no good reason, supposing cases can be found analogous to that of the moon, where the effects, though contributed to by many, are principally due to one or two causes, why, in sociology as in astronomy, there should not be isolated theories, the approximate character of their conclusions not being lost sight of. M. Comte, however, contends that the cases are not analogous, and that in sociology the isolation of effects and their specific causes is strictly inadmissible. Such sub-departments of social science have, notwithstanding, been formed. For instance, political economy is isolated from general social science, and devoted to the investigation of the laws of the creation and distribution of wealth—its approximations resting on the operation of a single law of human nature, that men prefer a greater gain to a smaller. Among the sub-departments thus formed or projected, is political ethology (Mill's *Logic of the Moral Sciences*), the science of the causes which determine the type of character belonging to a people or an age. This science investigates the effects of institutions or social arrangements upon national character and conduct, and thus corresponds immediately to the legislative art.

Political
ethology.

Sociological problems come in one or other of two forms:—1, Given a certain general condition of social circumstances, to determine the effect of a given cause; or, 2, What are the laws which determine the circumstances themselves? Sociology, as a science of tendencies, answers the first, by demonstrating the tendencies of particular causes under assumed conditions of circumstances: when the actual conditions differ from these, the practitioner, recurring to the principles of the science, must endeavour to take the omitted circumstances into account, or to omit the superlative circumstances, as the case may be. It answers the second by investigating the laws by which one state of society generates another. With regard to the first, Mr Mill is of opinion that it would be an error to suppose that, by deduction from the principles of human nature, we could arrive at any great number of propositions which will be true in all societies without exception. "Such a supposition," he says, "would be inconsistent with the eminently modifiable nature of social phenomena, and the multitude and variety of the circumstances by which they are modified—circumstances never the same, or even nearly the same, in too different societies, or in two different periods of the same society. Every cause, as its effects spread through society, comes somewhere in contact with different sets of agencies, and thus has its effects on some of the social phenomena, differently modified; and these differences, by their reaction, produce a difference even in those of the effects which would otherwise have been the same. We can never, therefore, affirm with certainty, that a cause which has a particular tendency in one people or in one age, will have exactly the same tendency in another, without referring back to our premises, and performing over again for the second age or nation that analysis of the whole of its influencing circumstances which we had already performed for the first. The deductive science of society does not lay down a theorem, asserting in one universal manner the effect of any cause; but rather teaches us how to frame the proper theorem for the circumstances of any given case. It does not give us the laws of society in general, but the means of determining the phenomena of any given society from the particular elements or data of that society." The

consideration of the second form of the social problem is less necessary to our purpose than that of the first, and would lead farther into the methods of general social science than is consistent with the limits of this article.

Legisla-
tion.

It will by this time be seen that the function of sociology is to supply the legislator with general rules and principles for solving particular practical problems; and that there can be no science of law separate from the science of society. When the legislator has to act in any case, he may consult the science as to the consequences of his acting in a given way, or as to the way in which he should act to accomplish a proposed end; as to whether the end proposed is itself practicable and desirable, or as to what end it would be most desirable to accomplish, looking to the good of society. Legislation is the art of applying the middle principles of sociology; and the general rules which it borrows from the science, together with certain art-principles of its own, make up its whole theory.

II. It remains to consider the nature and limits of the modifications of social phenomena producible by legislative measures.

There are here two guiding principles,—1, That events subjected to invariable laws are susceptible of modification in proportion to their complexity; and, 2, That the changes are producible by affecting their intensity and secondary operation, but not their nature or filiation. The postures into which an automaton may be thrown increase in number with the number of its joints, while each joint definitely prescribes a peculiar motion to the portion of the figure in which it is situated, and, in a degree, determines the fashion of all the postures. When there are many joints, an indefinite number of postures are readily producible, while it is vain to attempt to throw the figure into any one for which a single joint would have to yield a motion contrary to its nature. The case of a ship at sea, moving between the points up to which it can be made to sail to the wind, illustrates the same principles. In this, and every case of a combination of causes, the producible modifications are more numerous and easily effected the more numerous the causes are, and the ways in which they may be resolved, so as to vary their joint effect.¹

Coming now to legislative action on the complex phenomena of society, the former principle guarantees its facility, while the latter assigns its limits. It may be stated, in general terms, that it is limited by the sociological laws of harmony and succession; and that, within the limits prescribed by them, it must operate by affecting their intensity and secondary operation. This is no more than is intended by Adam Smith (*Moral Sentiments*, vol. ii., p. 84), when, in terms equally general, he describes the man of system as going on "to establish his plan of government in every point, as if he could arrange the members of a great society as he could arrange chessmen, neglectful that each has a principle of motion of his own." "For the rest," to quote M. Comte (*Philosophie Positive*, vol. iv., p. 404), "having ascertained the existence of general limits of variation peculiar to social phenomena, and especially of the modifications dependent upon systematic political action, and the scientific principle which is to give the character and limits of such modifications; it belongs to the direct development of social science to determine, in each case, the influence and actual reach of this general principle, by a special appreciation of the corresponding situation. It is by such appreciations, made empirically, that those men of genius who have really exercised a great and profound influence on humanity, in any way whatever, have been guided."

The limits
of legisla-
tive action.

¹ Accepting the definition of evil, that it is the result "of the non-adaptation of constitutions to conditions," the consciousness of our power to modify phenomena so as to accommodate constitutions to conditions, within certain limits, must be accepted as the ultimate source of our feeling of responsibility. The legislator's duties and responsibilities unquestionably depend on his having the power to determine the course of social events more happily than they would be determined in the natural progress.

Legisla-
tion.

Looking exclusively to the conditions of the existence, the cohesion, and coherence of society, it is possible to assign a few of the limits beyond which laws cannot, at least with safety or impunity, be pressed or relaxed. (1.) The first of the former class are determined by the conditions under which men live and propagate their kind. Some of the Roman jurists, perceiving that legislation could not be pressed beyond the limits set by these conditions, gave to a rule, based on their observance, the name of *jus naturale*. To this they referred,—1, The right of self-defence; 2, Liberty; 3, Common property in the air, water, &c., as conditions of the existence of individuals; 4, The union of man and woman; 5, The procreation of children; and, 6, Their education as conditions of the existence of the species. It seems to have been the opinion of Ulpian, that the *jus naturale* could not be infringed beyond a certain point without fatal, or, up to that point, without pernicious consequences. The limit might be partially transgressed, as in the institution of slavery; but not safely or consistently with the public welfare. (2.) A second, if less obvious limit is set by the conditions of popular health, mental and physical. Unless the restrictions on the actions of the people, set by the laws, be compatible with the healthful exercise of their physical and mental faculties, these will decay, and the people become stupid, brutish, weak in mind and body, and unfitted for the cultivation of the arts, both of peace and war. A society, governed by such cramping rules, will either decay, or fall before foreign enemies; or the people, throwing off their bonds, will constitute it anew. (3.) A third limit seems to be set by the conditions of popular activity in the directions of agriculture and commerce. The laws must allow to the people such property in land, and in the profits of trade, as will stimulate them to these pursuits. (4.) A fourth limit is set by the conditions of the sovereign's authority. These seem to be three in number,—1, There must be a system of education, disciplining the subject to merge his individual good in that of the state; 2, There must be among the people a feeling of loyalty; and, 3, A feeling of nationality. If the legislator destroys the subject's respect for his authority, or interrupt the process of discipline on which that respect and the love of country depend, he endangers his own power and the state's existence.

The preceding limits are likely to be pressed upon only under despotic governments; those now to be indicated may be approached under any government, and are not so easily assigned. Speaking generally, they are the limits beyond which the law cannot safely be relaxed. No society can hold together without laws, or usages with the force of law, to give reality to the conceptions of morality. The question is, what relations of the subject may, with safety to the state, be left free of legal regulation. The question, in this form, is too broad to be answered. But relations may be specified which cannot safely be left without regulation, and thus the question may be answered indirectly. We said that the laws must permit the union of the sexes; here we say that they must regulate that union by defining marriage, the modes of constituting and dissolving it, and its consequences. We said that the laws must permit the existence of private property; we say here that they must define it, and regulate the modes of its transmission and alienation, and give security, in its enjoyment, to its owners. If Proudhon's doctrine had been realized in France, it would have been a case of the relaxation of law beyond a limit of legislation.

Many limits might be conceived to be set to legislation by the character of the people in different states. In a country where, under a free government, the people are frank, outspoken, and loyal, if not always cautious in their language, the dogmas of the freedom of the press, liberty of conscience, and the sovereignty of the people, set limits to legislation,

which in other countries do not exist. Opposite limits, in fact, would be set to legislation in a country where the people were excitable, visionary, easily led by novel ideas, and lived under a despotism. If in such a country the laws were relaxed to permit the freedom of the press, government and social order might be endangered.

Over-legislation.—The consideration of the limits beyond which the laws ought not to be relaxed is closely allied to the inquiry, What are the relations which ought to be exempted from legal regulation? The answer, in general terms, is, that they are those with which the state cannot beneficially interfere, or which can be regulated with equal or greater advantage by the people themselves. What these are cannot be generally defined. They must be discovered by an appreciation of the whole circumstances of the particular cases, the propriety of interfering with which is questioned; and this appreciation must include the secondary and more remote consequences of instituting laws for these cases. A law designed to eradicate evils due to one relationship being without rule, may, by disturbing others, induce collateral evils which may, on the whole, exceed those it eradicates. Such relationships may be more beneficially regulated by the people themselves than by law, their rules changing with those who enter into them, as in the case of the commercial relation which the free-trade agitation in this country lately relieved from legal restraints. As discovery is made of the relations which may beneficially be freed from state control, the laws will obviously diminish in number. It is in this view that Dugald Stewart observes, that it might easily be shown that the greater part of the political disorders existing among mankind rise from politicians "having trusted too little to the operations of those simple institutions which nature and justice recommend; and, of consequence, that as society advances to its perfection, the number of laws may be expected to diminish instead of increasing, and the science of legislation to be gradually simplified."

The number of laws will also diminish as legislation is freed from empiricism. The empirical procedure makes legislation endless; it demands a measure to meet an evil, and a measure to meet an evil produced by a measure; and so on, till the legislature, restlessly touching society on all sides, increases beyond calculation the complexity of its phenomena, and its own difficulty in acting upon them; and till society, over and above its natural laws, which are few and simple, finds its action restricted by 20,000 statutes and 100 volumes of common law decisions. "Society, a living, growing organism, placed within apparatuses of dead, rigid, mechanical formulas, cannot fail to be hampered and pinched" (Herbert Spencer, *Over-legislation*). It is in view of the evils of much legislation on empirical principles, that Mr Spencer, in his able essay on the subject of this section, maintains that the primary state duty is to protect each individual against others; that to this it should be confined; and that all state action with the view of protecting individuals against themselves must be prejudicial. "Badly," he says, "as government discharges its true duties, any other duties committed to it are likely to be still worse discharged. To guard its subjects against aggression, either individual or national, is a straightforward and tolerably simple matter; to regulate, directly or indirectly, the personal actions of these subjects is an infinitely complicated matter. It is one thing to secure to each man the unhindered power to pursue his own good; it is a widely different thing to pursue the good for him. To do the first efficiently, the state has merely to look on while its citizens act; to forbid unfairness; to adjudicate when called on; and to enforce restitution for injuries. To do the last efficiently, it must become an ubiquitous worker, must know each man's need better than he knows it himself; must, in short, possess superhuman power and intelli-

Legisla-
tion.

Legisla-
tion.

gence." That there is much truth in this view might be established on consideration of the official laws which form the bulk of the legislative enactments of our own parliaments. But admitting that empirical politicians do, and must continue to, commit many mistakes in extending state action beyond what is ordinarily conceived to be the sphere of the administration of justice; and that many social relationships ought to be exempted from legal rule; we are far from assenting to the general proposition maintained by Mr Spencer, in the sense in which he maintains it, viz., that "till social requirements are fulfilled in a spontaneous way, they should not be fulfilled at all." The examination of the reasoning on which this doctrine is rested is the more necessary, from its being held to be fundamental by a growing school of politicians.

Mr Spencer's argument, which it is impossible to represent here in full, is briefly as follows:—Legislators, to act beneficially on society, should satisfy its wants in the order of their importance. But "to select out of an immense number of minor wants, physical, intellectual, and moral, felt in different degrees by different classes, and by a total mass, varying in every case, *the want that is most pressing*, is a task which no legislature can accomplish." Therefore legislators can never beneficially interfere to satisfy the minor wants of society; and, therefore, till such wants are satisfied by social vitality, they should not be satisfied at all. If this argument is well founded, legislation should be abandoned in every state advanced in civilization, and in which, of necessity, all the leading wants of society have already been satisfied. But it is not to be admitted that the mischief occasioned by state action arises from its liability to satisfy less social needs before greater. Mr Spencer has, in our opinion, in no instance clearly traced the evil of measures to their satisfying the needs of society out of their order; and, besides, his doctrine on this point appears to rest on grounds far too narrow to support it, viz., "that to effect a neglected thing by artificially employing citizens to do it, is to leave undone some more important thing which they would have been doing." The argument here turns (1.) on the presumed withdrawal from "social vitality" of the few officials needed to accomplish public objects; and, (2.) on the assumption that social vitality always satisfies social needs in the order of their importance. The presumption on the first point surely should be, on his own principles, and considering the comparatively small numbers of public officials, that "the more important thing" will be independently effected by social vitality. On the second point, we object that, supposing the assumption to be strictly correct, it extends to minor social needs, and the order of their satisfaction, through state agencies. The separation of the phenomena of legislation from the general phenomena of society is altogether inadmissible. The protest which Mr Spencer and others have raised against much legislation may have a healthful influence on the disposition at present prevailing in this country to trust to state action principally, or solely, for remedying social evils; but, judging from the facts, there can be no doubt of the vigorous existence of that disposition, and, so far, that the extended state action complained of is but an instance of social effort administering to social desire. But, granting the distinction between the cases of the leading necessities and minor wants of society, by which Mr Spencer meets this objection, to be good, it is untrue that the "minor" desires of society do, in the actual course of things, get satisfied in the order of their strength and of the importance of the wants to which they correspond. The order of actual satisfaction depends, in a secondary degree, upon the relative strength of desires, and, in a primary degree, on the opportunities that occur, or may be created, for their being satisfied. The strongest desire stimulating to activity to produce its opportunity, is satisfied after the weakest that grows up on an opportunity presenting itself.

Legisla-
tion.

In this view, while the social activities in different directions are proportioned to the strength of the desires which induce them, collateral circumstances conspire with them, and make the order of satisfaction different from what it would be if dependent solely on the degrees of activity. Though then it were to be desired in acting on society, that satisfaction should be given to its needs in the order of their importance, it would be strictly impossible always to satisfy them in that order, because of the conspiracy of causes by which the social harmony is constantly secured. But to conclude from this that state action following any other order must, on that account simply, be mischievous, and that such action should therefore, beyond a narrow conception of the sphere of justice, be altogether suspended, seems to be a serious error. On similar premises, a similar conclusion, applicable to family groups, would, in a large measure, arrest systematic efforts at education of every kind, and forbid individuals to mutually assist one another.

So far as the legislator is concerned, justice is the disposition to do whatever the good of society requires to be done; and that this is more than to stand by and see fair play between the subjects in their transactions touching property, and their principal personal relations, is evident from many acts of beneficial legislation that readily suggest themselves. For example, the ravages committed annually by small-pox in this country, and the culpable neglect, or the ignorance, of the laws of self-preservation, which led large classes of the people to omit vaccination, and consequently to endanger their own lives, and those of others, presented a proper conjunction of circumstances for legislative intervention. The law passed relative to that conjunction to save certain sections of the people from the consequences of their own ignorance or recklessness, operated to save others, better informed and more prudent, from danger. It was a simple case of justice; for our personal security ought to be guaranteed as well against the consequences of men's stupidity and folly, as against those of their passions; and laws protecting society, by making the improvidence of individuals penal in certain cases, are really, though not morally, in the same category with criminal laws. The same example furnishes proof that it may be necessary in some cases to satisfy desires out of the order in which they actually manifest themselves. Multitudes omitted to have themselves vaccinated, though in most districts provisions existed for having the operation freely performed. The desire of life, stronger than all others when life is in immediate danger, is one of the weakest in providing for distant contingencies, readily yielding to the aversion to a small exertion for a remote benefit; and the want of laws for the protection of health, measured by it, is accordingly small in periods of popular health. But in providing for this want at such a time, the state satisfies a need which then, indeed, is less than many others, but which becomes the greatest of all, when disease invades the people. In fact, it appears to be one of the leading duties of the legislature to aid the spontaneous action of society in that class of cases in which experience shows that the people are liable to sacrifice their true to their immediate interests. Granted that the mode of solution of all social problems must be experimental; yet the lessons of experience become manifest long before itself becomes painful enough to compel men to reduce them to practice. And although experience will ultimately lead the people to adopt, of their own accord, the rules necessary to be observed under their circumstances, yet surely it is the duty of the legislator to save them from the pains of experience, wherever his foresight enables him to do so, by prescribing these rules to them at once.

"It is," says Burke, "one of the finest problems in legislation, and what has often engaged my thoughts, whilst I followed that profession, 'what the state ought to take upon

Legisla-
tion.

itself to direct by public wisdom, and what it ought to leave, with as little interference as possible, to individual discretion.' Nothing, certainly, can be laid down on the subject that will not admit of exceptions, many permanent, some occasional. But the clearest line of distinction that I could draw, whilst I had my chalk to draw any line, was this,—that the state ought to confine itself to what regards the state, or the creatures of the state, namely, the exterior establishment of its religion; its magistracy; its revenue; its military force by sea and land; the corporations that owe their existence to its fiat; in a word, to every thing that is *truly and properly* public; to the public peace, to the public safety, to the public order, to the public prosperity. In its preventive police, it ought to be sparing of its effects, and to employ means, rather few, infrequent, and strong, than many and frequent, and, of course (as they multiply their puny politic race, and dwindle), small and feeble. Statesmen who know themselves will, with the dignity which belongs to wisdom, proceed only in this, their superior orb and first mover of their duty, steadily, vigilantly, severely, courageously: whatever remains will, in a manner, provide for itself. But as they descend from a state to a province, from a province to a parish, and from a parish to a private house, they go on accelerated in their fall. *They cannot do the lower duty; and in proportion as they try it, they will certainly fail in the higher.* They ought to know the different departments of things; what belongs to laws, and what manners alone can regulate. To these, great politicians can give a leaning, but they cannot give a law. Our legislature has fallen into this fault, as well as other governments. All have fallen into it more or less." Even the limits here, vaguely enough defined, are, or at least some of them, too wide and general. The fact is, no general limits are here assignable. As already stated, the duty of the state must be pronounced on from case to case, on an appreciation of the whole circumstances of cases, and calculation of the probable effects on society of state interference with them.

III. *Jurisprudence and Legislation.*—We must here, for the sake of completeness, give a brief account of the different senses in which the terms Legislation and Jurisprudence have been employed by different writers, and indicate the divisions of our subject which remain for discussion.

The words jurisprudence and legislation have been employed in many senses. Legislation at one time denoted the science explaining the principles from which law ought to be universally derived, and their application to particular countries; recently it has been employed to represent that portion of the law of a state directly derived from the supreme authority in its legislative capacity; and in this sense it is distinguished in France from jurisprudence, or that portion of the law derived from judicial decisions. In the former sense, again, legislation, or the science of law as it ought to be, has been distinguished from jurisprudence, or

the knowledge of law as it is (Austin's *Province of Jurisprudence*). On the other hand, jurisprudence, or *jus* (Whewell's *Elements of Morality*), has, both of old and recently, been employed to signify the doctrine of rights and obligations, or the science of law; and legislation to signify the art of applying the principles of the science of law (Bentham, *Fragment on Government*). In this latter sense, jurisprudence, under the qualification of "natural" or "universal," has had various provinces assigned to it. Adam Smith (*Moral Sentiments*, vol. ii.), speaking of the civil and criminal laws of particular countries, observes, that the principles upon which those rules either are or ought to be founded are the subject of the science of natural jurisprudence. The same functions have been assigned by various writers to universal jurisprudence, which again has been limited by others to the investigation of the principles common to the laws of all countries. Sir James Mackintosh uses jurisprudence by itself in the sense assigned above to universal jurisprudence, and again in a sense in which it is difficult to say whether he does not mean it to stand for the whole body of municipal law (Sir James Mackintosh, *Study of the Law of Nature and Nations*, Works, vol. i., p. 381). Carmignani, again, uses the word legislation to signify "the science of establishing law," and thus distinguishes it from jurisprudence, or "the science of the application of law;" and this is the sense in which Mr James Mill uses the word jurisprudence when he says that it has nothing to do with the constitution of rights, or the adapting them to the requirement of universal benevolence, but that its object is to show the best means of protecting rights that exist, whatever they are.

Not to dwell on the misuse of the word "science" in most of the above cited applications of these terms, it has been shown that, strictly, there can be no science of law separate from the general science of sociology. Political ethology converts the theorems of social science into rules of policy, and legislation is the art of applying these rules to particular cases; and the general rules and maxims of policy derived from the science, together with its peculiar art principles, make up the whole theory of legislation. The part of this theory derived from the science must differ for different societies as their states differ; but the principles of law-making—the art rules of legislation—rest on the general laws of human nature, and are everywhere the same. The rules of jurisprudence have the same generality, its principles being maxims of reason based on experience of what is essential to the protection of rights, whatever they are. Parting here, then, with the theory of law as connected with social science, and assuming the rights which ought to be established to be ascertained, two topics remain for consideration; the mode of establishing rights, to be considered under the head "Law-making;" and the mode of protecting rights, to be considered under the head "Jurisprudence."

Legisla-
tion.

PART III.—LAW-MAKING.

Under this head is to be considered how the constitution of the legislature affects its operations, and how laws may best be authenticated, promulgated, and preserved.

I. From the fact that practical and speculative talents are rarely combined in the same men in the highest degree, the practice of legislation ought to be separated from its theory, the practical function falling to the man of affairs, the consultative to the man of science. Between these, however, there should be perfect sympathy and mutual reliance, to secure what Mr Macaulay calls "the just temper of practical and speculative" which should characterize the perfect legislature. If the scientific authority necessary to secure this sympathy existed, the legislature would naturally divide

itself into the following departments:—1, Statistical, taking cognizance of the state of society; 2, Propositional, suggesting ends as desirable under the circumstances of society; 3, Solutional, applying the principles of science to determine how these ends may best be secured; 4, Practical, employing the art-rules of legislation in embodying in laws, and giving effect to, the recommendations of the solutional department. Of these departments, the first and third would fall to be presided over by men of science; and the second and fourth, by men of affairs. It is needless carrying this conception of a legislature farther, as there nowhere exists a sufficient weight of settled belief on social subjects to make its realization possible. Pending the creation of a scientific

The legis-
lature.

Law-making.

authority on these subjects to repress the tendencies of despotism on the one hand, and popular passions on the other, there is little chance of legislative action being anywhere very wisely or consistently prosecuted. Should such an authority ever arise, it will, in effect, destroy the distinctions of governments. Notwithstanding the opinion of Hobbes, that men would deny the propositions of geometry, if they anywise affected their interest, it is the fact that conclusions from these propositions are never questioned, though daily applied to human affairs. It cannot escape observation either, that in our own legislature contests no longer occur on questions on which even the imperfect science of political economy has unequivocally pronounced. As social questions are rescued from conjecture and empiricism, the area of political agreement widens. Co-operation is facilitated by the clearness of common interests, and the manifest convergence in the distance of opposite immediate interests.

Opposition of the conditions of civil and political liberty.

At present, it is only under a despotism that a principled course of legislation can be pursued; that is, *primâ facie*, the circumstances under which civil liberty could be made most nearly perfect, leave no security for its preservation. The conditions of civil and political liberty are, from the nature of things, in a large measure, opposed to one another. The one is identified with good laws, in security for which the other consists; and almost every condition of beneficial legislation is a relaxation of this security. This security must consist in such a distribution of political authority as that it shall preponderate in no person or class, so as to be exercisable to the prejudice of other persons and classes. Suppose political authority to be equally distributed, the people must, in order to having a legislature, delegate their authority to a few of their number. On this the security, looking away from the influence of public opinion, is measured by their power of making their representatives attend to their wishes; and this practically by the frequency of elections. But the more frequent these are, the more difficult it is to secure qualified legislators, and continuity in legislative operations. The security, again, is greater the less the separate constituencies are. But the less these are, the greater will the legislative assembly be, and the less its capacity for concert and deliberation. The choice, then, is between a small legislature and security, and a large legislature, forced by its unwieldiness to repeat the process of representation, and entrust affairs to a ministry capable of being influenced only at second-hand by the people; in which case, likewise, the security is diminished. In the second case, the conditions of good government are repeated: the assembly must relax its control over ministers. Ministers, again, for the right conduct of affairs, must divide the departments of the administration between them, and be each left free, to a considerable extent, in the conduct of his department. So far the conditions of obtaining good laws and government are relaxations of the security for them, and make it almost imaginary. But, even when it is thus relaxed, the form in which it is taken is unfavourable. Majorities only being represented, the legislature is only partially representative of the people; and, again, majorities of the representatives determine the course of legislation. So that social evils pressing on the minority, or even on the whole community, may long go unredressed, if, in the one case, a majority of the people, in the other of the representatives, would be inconvenienced by redressing them. The action of constituencies on representatives, again, tends to convert what should be the deliberative assembly into the scene of conflicts of immediate interests rather than reasons; and in harmony with the character of the legislative assembly are the means resorted to of influencing its proceedings,—political agitations without it, and party combinations within it. In the absence of a sufficient authority on public questions, principles are loosely held, and readily yielded to the necessity of com-

Law-making.

bining to carry particular measures. In the balance of the conservative and movement parties, small knots of men obtain an influence on legislation wholly disproportioned to their numbers and the interests they represent, and this opens the way to political immorality. Ministers, overtaken with the duties of their departments, and having, in the fever of party struggles, to initiate legal and social reforms, approach divisions on grave questions only after exhausting ingenuity in delays, among the means of obtaining which is excessive petty legislation; and in the struggles of parties, interests on which the people cannot easily be excited—those related to the administration of justice, for instance—are neglected. Great measures are passed only in an excited and unwholesome state of the body politic; and the alternative is between state inaction and state activity when all the circumstances are unfavourable to reasonable legislation. While deplorable defects in legislation are thus traceable to constitutional securities for good laws and government, what is, after all, the chief security for the latter—the facilities for promptly bringing public opinion to bear on public men, and the sensitiveness to that opinion which, in the history of a free country, has been developed in them, is not a whit more favourable to good legislation; public opinion being itself generally as divided as opinion within the legislature. But if political liberty be thus unfavourable to civil liberty, it keeps alive the spirit of independence and the energies of the people, and makes them prosperous in defiance of bad laws. It has been truly observed, that the sense of security and independence is as essential to the advancement of society as to the comfort of individuals; and, without seeking unduly to disparage the laws of England, she may be instanced as an example of a nation maintained in her rank by the feeling of freedom, in spite of grievous defects in her institutions and laws, incidental to the modes in which her people have had, historically, to struggle for, and maintain their liberties. And, in fact, it is a question, for the satisfactory settlement of which there are no sufficient data, whether, in the present state of our knowledge, the whole phenomena of a nation could be more beneficially determined under the wisest and most benevolent despotism than amid the struggles of opposite interests under a popular government.

It would be out of place here to do more than glance at the subject of government, with which the inquiry into the constitution of the legislature is allied. The reader must refer to the article on that subject. But, in conclusion, of the brief, and necessarily unsatisfactory remarks here presented, it is necessary to repeat, that the main distinctions of governments will disappear should science ever rescue social questions from the waste of opinion. Such a government as our own will then show to the greatest advantage. The importance of the separation of legislative, judicial, and executive functions, characteristic of a balanced government, will then most clearly appear; the inclination to despotism as favourable to good legislation will be removed in the presence of a scientific authority; and with the means of obtaining good laws, we shall have ready provided the best means of administering them. In the transition state, a balanced government, as compared with a despotism, is what a raft is to a ship. The one, trim and rapid in its movements, sails up to the sunken rock on which it strikes; while the other, unsteady and oscillating in all its parts, but safe in the inherent coherency and buoyancy of its materials, passes on always with perfect security, though in constant and immediate contact with the source of danger.

II. The evils arising from judge-legislation have been Judge-frequently, ably, and eloquently exhibited during the last half century; but it is fitting that the question respecting legislation. it should be here discussed, because it bids fair to continue for some time to be one of public interest. For the same

Law-making.

reason it is here considered in its relation to the state of the law in our own country.

The common or unwritten law.

The common law is embodied in a great number of written and printed records—the reports of decisions of courts of justice pronounced from time to time over centuries. But though its rules are enacted for cases as they occur, the fiction is that they have existed from of old, and are not enacted but declared. According to this fiction, common law consists of a published and unpublished part—the latter latent and unknown till declared; while the former, though declared, can scarcely be said to be known, for it is liable to be made to give place to newly-discovered portions of the old law. The judges who declare its rules do not know them relative to new cases till they have decided them. When such cases occur they have to make inquiry what the law is. In this inquiry they are guided by the analogies of the new cases to old ones. The pleadings before them are, as Paley observes, “a competition of opposite analogies,” the best of which are entitled to prevail. When the analogies are few and faint, they decide the case according to their notions of the requirements of “reason and justice” respecting it; and having once pronounced a decision, they are bound to adhere to it, unless it be “flatly absurd and unjust” (Blackstone’s *Commentary*, vol. i., p. 70), of which themselves are the sole judges. So that at any time they may make new rules, and unmake old ones, provided they can bring themselves to consider them absurd and unjust.

Objections to judge-legislation.

The objections to this species of legislation have been brought by Sir Samuel Romilly under six heads. 1. Judge-made law is necessarily an *ex post facto* rule. “It governs all past as well as all future transactions. Property, which has been purchased or transmitted by descent to the present possessor of it, is discovered by the newly declared law to belong to others; actions which were thought to be innocent turn out to be criminal, and there is no security for men’s possessions, their persons, or their liberties” (*Edinburgh Review*, xxix. 228). 2. In making laws the judges are compelled to proceed almost wholly on technical reasons. “They are forbidden to entertain any of the considerations which ought most to influence the judgments of those who are avowedly employed in making laws. What will most tend to promote the general good, or what is best adapted to the present habits and modes of thinking of mankind, the judicial legislator is bound to disregard. He is to consider not what would be the best law on any given subject that could be made; but what law was most likely to have been made upon it at the remote period when the common law is supposed to have had its origin. All his researches tend to discover, not how the evil which has occurred may best be remedied, but in what manner it is probable that, in a very different state of society, the matter would have been ordered.” Hence the anomaly of the two main branches of law growing on opposite principles; the one, by analogies, drawing nourishment from the judicial debris of centuries; the other expanding on the principles of expediency. 3. Judge-made law is an uncertain rule. 4. Judge-made law wants generality of application. The judge-legislator is forbidden to give a comprehensive rule. He must restrict the law to the particular case before him, and take the narrowest view of that case. He thus loses every opportunity that presents itself of giving a rule to include many possible cases as well as that before him; and while terminating a litigation, does little towards defining the law and precluding future contests—as analogous cases will be found to differ in some respects from one another, and from that decided. The opinions which he may offer on such cases in illustrating his decisions are treated by his successors as extra-judicial, and of no authority. 5. Judge-legislators may be, and often are, unqualified to legislate on particular cases, on which, however, it falls to them to legislate. The

branches of legal study are various, and the studies of most lawyers are special. When lawyers mount the bench they are esteemed qualified on all branches of law alike, and to legislate on all subjects whatever which chance may bring before them. 6. Judge-made law is made by men over whom the people have no control. “Our legislators here,” says Sir Samuel Romilly, “have been, not the representatives of our choice, but often the servile instruments of our monarchs.”

Law-making.

This species of legislation, however, has its advocates—Arguments in favour of judge-made law. especially among the judges. Successive governments have for more than twenty years held it settled that the unwritten criminal law at least should be reduced to statute; but the reform has yet to be accomplished. When the Lord Chancellor Cranworth, in 1853, submitted specimen criminal-law bills digesting the whole law relating to the definition and punishment of offences to the judges for their opinions, they, with one exception (Chief Justice Jervis), deprecated the attempt to reduce the unwritten law to statute.

“The rules of the common law,” said Mr Baron Parke, “are clear and well understood, and they have the incalculable advantage of being capable of application to new combinations of circumstances perpetually occurring, which are decided, when they arise, by inference and analogy to them, and upon the principles on which they rest.” “To reduce the statute law into a narrow compass,” said Mr Justice Talfourd, “is an object entirely free from objection, and which, if accomplished with care, can produce nothing but good; but to reduce unwritten law to statute is to discard one of the greatest blessings we have for ages enjoyed in rules capable of flexible application.” “It seems to me,” said Mr Baron Alderson, “to be a very unwise thing to abolish the common law principles of decision, which can accommodate themselves to the varying circumstances of the time; and thus, as it were, to stereotype them, by act of parliament, in verbal definitions, many of them inaccurate.” Lord Mansfield is reported to have entertained a similar opinion of its merits; holding that “the common law, which works itself pure by rules drawn from the fountains of justice,” is superior to an act of parliament (*Athyn’s Reports*, vol. i., 32, 33).

From their statements on the subject, we gather that the arguments in favour of this species of law are:—1, That it is prepared for all cases; 2 (which is the first argument in a different form), That its rules are capable of flexible application. While the objections to its reduction to statute are, —1, That its principles are so interwoven with the circumstances of cases that they cannot be taken up from their contexts and separately enunciated; 2, That supposing the unwritten law converted into statute, the uncertainties of the interpretation, to say nothing of the errors of its definitions, would exceed those of the law as it stands; and, 3, It is maintained by some, that the same degree of logical coherence as the common law possesses cannot be given to written law. The value of the arguments in favour of unwritten law will best appear in an examination of the objections to reducing it to statute, to which we pass on with the remark that at the worst, supposing written law cannot be made to meet all cases, the discretion which the judges now have would have to be left with them so far as concerns distinctly new cases.

The first objection is inconsistent with the assertion of the judges, that they find the common law rules clear, and easily applicable to all sorts of cases. It cannot be clear what the rules are, and yet be impossible to say what they are. In applying them the judge necessarily lifts their principles out of their old connection, and plants them in new circumstances; and, in explaining them, in applying them, he can neither come nearer to them, nor apply them more correctly than he has language in which accurately to express them. In other words, the errors in the judges’ application of the principles have for their measure, so far,

First objection.

Law-making.

the errors in their definitions of the principles. The question, then, is not whether the rules and principles can be defined with perfect accuracy, so as to be transferred in their integrity into statute; but is between the errors of the definitions in a written law,—the definitions being made by the men best qualified for the work, the body of judges themselves, for instance,—and the errors of the definitions of the same rules committed by the same men, individually, in applying them. There can be but one answer to this question; that definitions made, we may say, on the moment, are likely to be more erroneous than those made on consultation and deliberation; and that the errors commisable by judges, in applying common law rules, are, so far, likely to be greater than they might be if the rules were deliberately defined in statute. The alleged facility of judgment is incompatible with the impossibility of defining the law, unless, by the flexibility of its rules, it be understood that they readily take whatever shape the judges choose to give them. And, in fact, we are forced to understand it in this sense. It is not that the judges easily apply the rules of law,—that, according to themselves, cannot be done,—but *rules*, it may be, wrong in principle, but having the “incalculable advantage” of being easily applied. Their position is, that they do not administer law at all, but a species of equity.

The flexibility of the common law rules is one of the principal objections to them; so long as it exists, decisions must be capricious, and the law uncertain. Whoever has often heard the common law declared must be aware of the unsatisfactoriness of the reasons occasionally assigned for it; the words “reason and justice” filling up arguments based on shadowy distinctions, and on a few, selected from many, of the analogies presented by cases, on no principle, or one vaguely expressed. What Beccaria has said of the discretion of judges to decide according to “the spirit of the law,” applies to their making the law itself. “The spirit of the law,” he says (*Essay on Crimes and Punishments*, p. 22), “will be the result of the good or bad logic of the judge; and this will depend on his good or bad digestion, on the violence of his passions, . . . and on all those little circumstances which change the appearance of things in the fluctuating mind of man.” Selden’s condemnation of equity is also directly applicable. “For law,” he says, “we have a measure, and we know what we trust to. Equity is according to the conscience of him who is chancellor; and as that is larger or narrower so is equity. ’Tis all one as if they should make the standard of measure of the chancellor’s foot” (*Table Talk*). “Certainty,” says Lord Bacon, “is so essential to law, that a law without it cannot be just; . . . and it is a true maxim, that the best law leaves least to the breast of the judge.”

If, then, the definitions of written law may be made more closely to approximate to the full and accurate expression of common law rules and principles than the definition of the same rules and principles made by the judges in applying them from case to case; and if, by defining them, we in a degree destroy their present uncertainty, there can be no doubt so far as to the desirableness of transmuting the common into written law. Even were it not clear that the definitions may be improved, the certainty gained by fixing them would almost of itself atone for their imperfections, especially as these must soon appear and be amended.

Second objection.

As to the second objection, it is incredible that the analogies of cases do not offer wider scope for misjudgment and uncertainty than the meanings of statutory words. It is argued, indeed, as if the liability to error from the ambiguities of language lay wholly with judgments proceeding on statute. But the probable errors are less in interpreting statute law than common, because the ambiguities multiply with the words to be interpreted, and because the definitions of statute law are short compared with the ac-

counts of circumstances, and the comments of legists and judges, through which alone the common law rules can be known. No doubt, in reducing the law to writing, a discretion of interpretation must be given to the judge instead of that taken from him; but then its exercise will at once consume it, so that the new discretion will both be less dangerous and shorter lived than the old. And this is all that it concerns us to know. That the definitions of the written law can never be made perfect, or the discretion of the judge be wholly removed, is nothing to the purpose; it is sufficient that its imperfections, and the errors commisable in its application, may be made less than those of the common law as now administered. Those who glory in the capacity of the common law of “working itself pure” should not grudge to endow written law with a degree of the same capacity.

Law-making.

The coherency which can be given to written law, it is Third objected, is less than the unwritten law possesses. The question is, whether it is likely that a system branching from well-defined general principles into particular applications of them can be made to observe a greater logical coherence than is presented by a system that, beginning in rude and indefinite principles, has spread by the aid of analogies and technical reasons, under the superintendence of a great many minds of every shade of intellectual capacity and conscientiousness. The question contains its own answer. It has been well put by Mr Empson (art. *LEGISLATION*, 7th edit. *Encyclopædia Britannica*), who makes, for the sake of argument, a concession to the common law not due to it—that its original principles were general and sound. “Of the two presumptions,” he asks, “which is more probable,—that the qualities of systematic coherence and dialectic deducibleness will be the natural accompaniments of a system which branches from sound general principles into particular didactic regulations; or that they will be the artificial consequences of a fictitious system built on an interminable series of specialties called precedents, especially when it is considered that the very element of case law involves so many points of variation that, on any occasion, nobody can be sure that he is not exercising his logic upon a different set of precedents, or upon those specialties in the self same precedent which, after all, the judge may consider as not properly applicable to the case? There are embodied, in almost every precedent, opposite analogies, with sundry hanging threads attached to them, any one of which a judge, who is a little capricious, may lay hold of at his pleasure.”

III. The discretion left to the judges is only one source Unmanage- of the uncertainty of the common law; if they were per- able mass mitted to give comprehensive rules for general cases, its un- of the law. certainty would probably be less than it is. The rapidity with which case law accumulates may be judged from an inspection of the annual volumes of reported decisions. According to Blackstone, the common law was long ago so great that it could only be perfectly known by a twenty years’ study. No sensible man, even in the legal profession, now attempts to acquire a perfect knowledge of it; judges themselves are contented to know it at second-hand from unauthorized comments on conflicting decisions; and even the commentators occasionally disagree as to its rules. Nor is the mass of the statute law less. Every session of parliament adds to it often as many as a hundred statutes; which rarely cancel statutes previously in force on the same subjects, so as to be amended and uniform substitutes for them; but are commonly designed to amend acts that previously amended others; or to confirm and strengthen former statutes in like cases while adding or altering some particulars as to their operation. New statute rules thus rarely stand clear and intelligible apart from the mass of the law, but are welded into and lost in it; “whence sometimes follows that torture of Menutius

Law-making.

whereby the living laws are killed in the embraces of the dead ones." Even the projectors of the Criminal Law Bills, already referred to as designed to consolidate and digest the whole law relating to the definition and punishment of offences, thought fit to propose only partially to repeal thirty-one acts relating to offences of the thirty-three set forth in the schedules to the bills; and of those which they proposed partially to repeal, many they designed to repeal only in parts of sections. Of the 7th and 8th George IV. chap. 29, for instance, they would repeal only certain sections, and of these eighteen only partially. On this system of law-making, the more active our legislators are, the more confused the law becomes. "There are at this moment" (1842), says Mr Burton, "upwards of 130 statutes, more or less in force, in regard to the stamp laws;" and since he wrote legislation on stamps has been active. It is thus that the statute law is brought into as great uncertainty as the common law. The number of statutes is now ten times greater than when Bacon complained, "So great is the accumulation of the statutes, so often do they cross each other, and so intricate are they, that the certainty of the law is lost in the heap." When we look at the accumulation since his day, the story will be credited of a four days' debate by learned advocates before a Master of the Rolls (Sir William Grant) on the interpretation of a statute, which was afterwards discovered to have been repealed! As will (in view of the uncertainty of the common law) the truth of the report of a saying of Lord Eldon (Earl of Radnor *v.* Shaftes, 11 *Vesey*, p. 453), "Having had doubts upon this will for twenty years, there can be no use in taking more time to consider it!" Of a piece with which is the exhibition of the ignorance of the law recently made by the legislature itself. Long debates took place in the sessions of 1854-55 and 1855-56, on a bill to amend the existing law (Mr Lowe's Partnership Amendment Bill) before certain persons of high "legal authority," after "much consideration," concluded that, "by the analogy of cases, the rule to be introduced by the bill was already in the law!"

The Specialty Character of the Law is at the root of this confusion. We have too many laws for particular cases, to amend clauses of special laws, and to amend laws that amended others. This is partly owing to the specialty character of our institutions, the laziness or want of system of legislators, and the peculiar constitution of the legislature; but principally to empiricism. The tit-bit procedure necessitated by empiricism, by augmenting the labour of legislation, prevents the law attaining the perfection which, even on empirical principles, it might have. Empiricism encourages attempts to cope with casual circumstances by small measures to meet evils incidental to others, and which, if left alone, would cure themselves, or which can be cured only by striking at the greater evils. The special, again, work up against the general laws, are soon found not to work well, and are tinkered to shape them to the latest views. The state of the law is, in short, the natural consequence of the system of rules which Mr Macaulay represents the legislature to have followed from the age of John to Victoria. "To think nothing of symmetry and much of convenience; never to remove an anomaly because it is an anomaly; never to innovate except where some grievance is felt; never to innovate except so far as to get rid of the grievance; never to lay down any proposition of wider extent than the particular case for which it is necessary to provide." It is satisfactory to be able to record that, of late years, the disposition to depart from these rules has been acquiring strength, under the pressure of the accumulation of small inconveniences occasioned by so long following them.

Law-drafting.—The bulk of the law is farther increased by the redundancy of its language. The evils of bad law-drafting have been ably exhibited by Mr Symonds, in his

Law-making.

Mechanics of Law-making, where he shows that the mass of the law is greatly owing to—1, The precise over-specification of non-essentials in acts of parliament; 2, The constant repetition of the same words, their doubles and equivocations; 3, The constant reiteration of all the qualities, incidents, and relations of a thing, as often as its name is repeated; 4, The confused structure of clauses; 5, The unscientific method of drawing acts. We must add, that the bulk of the statutes is farther swollen by redundancies of substance. Provisions for carrying laws into operation, for instance, instead of forming a separate law of procedure applicable to whole classes of statutes, are frequently brought into the statutes individually. No idea can be formed of the extent to which our 18,000 statutes might be reduced by the simple operation of stripping them of these redundancies. As it is, the absence of facilities of reference to the statutes—the last defect of law-drafting to be noticed—aggravates the evils due to their number and bulk.

Law-literature—Justice could scarcely be administered in the existing state of the law, if the accounts of it by unauthorized commentators were not allowed weight in courts of justice. But, on the natural law of supply and demand, private enterprise has partially made up for state inefficiency. Any work reducing the law on a class of subjects to a reasonable compass is readily grasped at. The commentators, referred to at first from convenience, come at last to be authorities in courts of law; and institutional or law-literature seriously undermines the authority both of the legislature and judge-legislators. Nor is an extensive acquaintance with the commentators necessary to assure one that the uncertainties of the law are fully reflected in their works; often they merely conjecture what the law is—balancing the authorities of names, and adjusting conflicting analogies. The uncertainties, indeed, are often slight, but sometimes they are absolute; and even slight uncertainties are fruitful sources of litigation. And then the superfluity of law-literature threatens to induce a similar state of matters to that in which its own authority originated. The books multiply so fast on the various branches of the law, that they will soon be as unmanageable as the law itself.

Civil Equity is in the case of the common law; and the efforts to procure its reduction to written law have been met by the same objections. In England it has long lost its original arbitrariness; that element dropping out with every exercise of judicial discretion. The arbitrariness left is a discretion in distinctly new cases; for the rest, the application of the principles of old decisions to analogous cases. In connection with civil equity must be noticed the jumble of jurisdictions as an additional source of uncertainty. To take a case lately before the public, three courts, proceeding on different principles, have jurisdiction in cases of intestate succession, and have no common court of appeal. To the uncertainties in the same court are hereby added those due to the concurrent jurisdictions of judges administering different principles. It is not, then, to be wondered at, looking to the state of the law, and to our system of judicial procedure—"a technical system invented for the creation of costs"—if we frequently submit to injustice from one another rather than risk the greater evil which it is in the power of the law to inflict on us if we set it in motion to do us justice.

IV. By codification is understood an authoritative consolidation of the whole law, in its leading divisions, giving it coherency and unity of principle, and making it the clear expression of comprehensive and consistent rules. That this reform is necessary, has been maintained by many of the best writers on the laws of England, by none more ably than by Bentham. The question of a code is one of fact, to be discussed in the view of the state of the law and the practicability of the reform. A barbarous age presents neither the materials for a code, nor the

Law-making.

generalizing spirit necessary for its construction; nor, such is the harmony of things, the necessity for its being constructed. But when the laws of a country present such rich materials as ours do, and in such confusion, nothing short of the radical reform implied in codification will suffice for them. We have passed the point attained in every country that advances far in civilization, when, in the growth of law, its exuberance impedes its natural functions, and it becomes imperatively necessary to prune it in all directions.

The principal objections to codification have been considered and rebutted by anticipation in the discussion regarding the desirableness and practicability of transmuting unwritten law into statute. If the law can be, and ought to be written, no one will assert that it ought to be written after the manner of our statute law, or deny that our statute law stands in need of systematization and consolidation. In fact, no one admitting the positions which we conceive ourselves to have established under the head "Judge-made law" can question the desirableness of a code, however he may doubt its practicability.

Its practicability.

The practicability of codifying the law might be proved by a direct argument on its conditions, to the effect, that no insuperable, or even very great difficulty, lies in the way of its being done; and the argument might be confined to the civil and penal codes with which the principal difficulties, such as they are, are confessedly connected. The difficulty of the civil code is that of defining and classifying rights; and of defining the facts which give them commencement, and put an end to them. Now rights, and the facts which begin and end them, are already in a way defined by the law. To the extent that this is well done, therefore, the difficulty is commensurate with that of knowing the existing law, and it is not for the opponents of codification to maintain that this is insuperable. The first operation in the process of codification is to bring the definitions of rights together in lists, according to the nature of the subjects to which they relate; the next is to arrange those of the same kind according to duration and extent. The difficulty of the former operation is diminished by the fact, that on the lists being partially formed, the rights set down suggest those to be added; and the difficulty of classification is diminished by the principles of law coming out, in the process, with great clearness, and throwing light on the arrangement to be adopted. When the lists are obtained, and their arrangement effected, what remains is to specify the facts that shall give rise to rights and end them. This has also been done by the law from case to case, so that the difficulty of it is commensurate with that of knowing the law; and when these facts are defined the code is complete. In none of these operations does there appear to be anything insuperable, or even very difficult to be done, although, no doubt, considerable perspicuity and logic would be necessary for the proper classification of rights. The penal code presents still fewer difficulties, being less extensive than the civil. What must be done is to define and classify crimes, to fix the penalties to be incurred by committing them, and to set forth the rules of law as to the incapacity to commit offences, &c. Crimes and their penalties, &c., being already defined by the law, the difficulty is again the same as that of knowing the law.

But the practicability of codification is above depending on an abstract argument on its conditions. Whatever the difficulties of it may be, they have been triumphantly surmounted, as in the Code and Pandects of Justinian, the Code Napoléon, and the Code of Louisiana, which were successfully made to embrace the leading rules and principles of the systems of laws which they were respectively framed to supplant. And while the Code of Louisiana, which has been in operation for nearly half a century, may be directly appealed to in proof of the practicability of codifying the common law, the Code Napoléon was far more

difficult of construction than an English code would be, because of the greater heterogeneity of the provincial usages which it had to reduce to system. If farther proof be wanted, we appeal to the commentaries from which our lawyers and judges know the law. What, in fact, are the commentaries, but successful partial attempts at codification? And will it be maintained that what private individuals do so well cannot be done more efficiently by the state? That codification is difficult, and cannot be perfectly executed, is nothing to the purpose. It is enough if it be possible to frame a code more perfect than any of the commentaries, and having authority. The Criminal Law Bills of 1853 may be instanced as proving the practicability of this, as they go far towards being a complete penal code, and are, in point of style and order, almost all that can be desired. The practicability of framing a penal code has, indeed, been conceded by many who hold the negative on the general question, but with what show of reason will appear from considering that the penal code, though not conterminous with the civil, presupposes the definitions of the major part of it, and of many of the rules of constitutional and official law as well.

The degree of perfection which may be given to the code will, of course, depend principally on the care, fidelity, and capacity, of the men selected to frame it. The steps in the operation of forming it would appear to be,—1, The classification of the statutes and of the unenacted law; 2, The consolidation of the statutes and digestion of the unenacted law; 3, The digestion and assimilation into one body of the consolidated statutes and digested common law. The principle of classification being previously adopted, the workers on the statutes and on the unwritten law might continue their labours separately over the first and second steps; in the second also, the labour might be lightened by division, the consolidation of each class of statute and common law rules being entrusted to single persons; the workers coming together again in the third stage of the process. In the last state of reduction, the best way would appear to be, clearly and briefly to set forth the general rules of law, and to follow them by specifications of the particular cases to which they apply. Great care would be required in all the stages not to allow any rule of law or principle of a decision to drop out; and then to have all disputed or doubtful points cleared up by enactment, and to have, by the same means, the contradictions and inconsistencies of the law rooted out. When the scaffolding by which the law has been erected has been cleared off and buried out of sight, and when it has been stripped of its redundancies of language and substance by the first and second operations; the third will be found to be far simpler than can now be conceived. It is not to be concealed, in view of the degree of organic unity which codification aims at giving the law, that the proposal to codify it is not a proposal to consolidate it merely, but to reform it as well. Whatever machinery were employed to consolidate it, would find no small part of the difficulty of its task to arise from its being restrained from reforming it; and in any attempt to classify the laws, their inconsistencies could not fail to appear. It is comparatively easy to obtain structural unity in the composition of harmonious materials, but it is impossible to obtain it in the composition of materials irreconcilable and discordant.

We cannot enter farther into the consideration of the machinery best adapted for codifying the law, than to remark, following high authority, that the separate divisions of the code could more readily and successfully be reduced to unity and order by single minds, than by several working together. Supposing men of the requisite capacity to be obtainable, they should be entrusted each with the department of the law of which he has most knowledge; one or more to follow in their tracks, rectify their mistakes, and fulfil their designs. Those engaged in the business would

Law-making.

Codification implies a reform of the law.

Agency for forming the code; difficulties of getting the code made and enacted.

Law-
making.

find again, that the tracks of the commentators who preceded them required only to be straightened here and levelled there to be perfect avenues to the law; so that the pains taken by private persons, in past times, to reduce it, might all be made tell towards its final reduction into the code.

Commissioners for the consolidation of the English law have now been at work for over twenty years, and the Criminal Law Bills of 1853 are, so far as we are aware, the only published practical results of their labours. We understand, however, that they have consolidated all the statutes relating to indictable offences,—with the exception of those connected with laws relating to bankruptcy, customs, and religion,—into six bills; and included in two (having finally abandoned the bills of 1853) the law relating to principal and accessory, and criminal procedure. For the rest they *expect* to be able to reduce our thousands of statutes into three hundred acts or thereabout, by rejecting from the statutes obsolete acts and acts of a special nature, and consolidating the rest. If they do even this, they will confer on the nation an inestimable blessing. But it must be admitted, that if the practicability of the code were to be measured by the smallness of the pretensions of the commissioners, after so many years' consideration of the work entrusted to them, and by the fruits of their labours over so long a time, the case would indeed be desperate. But whatever may be the qualifications of those employed on the commissions, it cannot be said that they have received much encouragement. The public scarcely believes in the sincerity of their undertaking; which is itself too narrow to meet with the full approbation of zealous legal reformers. The position is one of great difficulty; but it is clear that the difficulty is increased by the disposition of successive ministers to compromise the question of a code for a partial reform, and to postpone the realization even of that. Either our ministers want the largeness of view and the decision of the masters of men who have given codes to the world, or their tenure of office is too uncertain to permit of their energetically acting out their views, and they are naturally lukewarm in the prosecution of tasks the merit of completing which may accrue to others. Whatever be the explanation to be given of the fact, the instance can scarcely be said to have yet occurred of a popular government conferring the blessing of a code on its subjects. Supposing the task finished, the legislature is wholly unfit to judge of its merits, and must accept or reject it on the authority of individuals. In England, high authority on legal subjects is scarcely to be found in men not enjoying political importance; and the political lawyers are called on too laboriously to attend to their own and party interests to exhibit those qualities of head and heart which would dispose the legislature and the people to trust them, even if they could be induced to undertake so great a labour as would be necessary for successful codification. The only hope of the successful accomplishment of the reform lies in the creation of a strong public feeling in its favour by the repeated exhibition of the evils of the law.¹

The sub-
codes.

The code must consist of five sub-codes,—1, The constitutional code; 2, The official code; 3, The civil code; 4, The penal code; 5, The code of procedure. The subjects of the civil and penal codes, and the difficulty of constructing them, have received special consideration.

The advantages of forming the laws of procedure into a

separate code are apparent. For the rest, municipal or local police laws depend on the powers of magistrates of burghs defined in the constitutional code; while general police acts are a standing portion of the official code. The proposition to codify the official laws is not made without hesitation; but it is here the law is most special, cumbrous, and deficient in system, and that legislation is most laborious. The extent to which system and generality might be given to these laws has been pointed out by Mr Symonds, to whose work on the *Mechanics of Law-Making* the reader should refer on this subject. The laws relating to the revenue, which should in strictness form part of this code, produce social changes so suddenly, through the constant endeavour of the public to relieve itself of its burdens, and must therefore be changed so frequently, that it would be useless to attempt codifying them. The modes of raising the taxes also change with the taxes, so that neither the laws which determine the taxes, nor those which regulate the revenue machinery, can be other than ephemeral. There appears to be no reason, however, why the other laws of the public service should not be made general, permanent, and public. It would be in favour of administrative reform if they were. They are at present utterly incognoscible—the powers and responsibilities of departments and commissions lying concealed under their entire history. The necessity of codifying the constitutional laws need not be insisted on. Only one in a thousand has, at present, more than a faint general idea of the system of government under which he lives. If the improvement of that system is desirable in any respect, it would follow on its real character being known.

Law-
making.

That the code may be made perfect in its principles and appliances once and for ever is an idle fancy; the law can never remain in the rear of the civilization which it guards. Grown up with and out of experience, it must constantly change with it. All that can be aimed at is to round and compress the law relative to the experience of the past, and to start it afresh with provisions for its accommodating itself to the requirements of new times, without losing its accessibility and certainty. The question is with what provisions to equip it. Two sets of ends must be provided for; the first, for accomplishment at short intervals, are three in number: 1, The collection of materials for the growth of the code; 2, Their preparation for being incorporated in it; and, 3, Their incorporation into it; the second, for accomplishment at longer intervals, are two in number: 1, The revision of the code, and rectification of defects discovered in its principles; 2, The excision from it of rules found to be unnecessary or pernicious owing to social changes. Courts of justice must continue to be the principal garnerers of materials for the growth of the civil and penal codes. The imperfections of legal principles and definitions are most likely to be discovered in these courts, in which also cases not provided for arise for decision. It has been suggested that the judges should be bound to report on cases of hardship to which, through over-generality or particularity, the law appears inapplicable, their reports to be laid, at short intervals, before the legislature as materials for law reform; and that they should decide distinctly new cases as they best can, their decisions of them to be final, and their reports on them to be materials for general laws to include them. By these means the materials for the growth and reform of the law, so far as suppliable by

¹ The government is now said to be at last earnestly bent on the reduction of the whole *statute* public law of England to the consistency and dimensions of a practical code. The chief commissioner thus describes the procedure which he means to adopt:—"To take the statutes at large from Magna Charta to the last act of Victoria; to expunge and reject from the statute-book every act and every enactment which is either repealed, expired, or obsolete, and then to take what remains (which will consist of all that is law in force, and to continue in force), to digest and to arrange this body of law, by dividing it into classes, and sub-dividing each class into single subjects; and then to reduce the whole into single bills, each bill being on a single subject, but comprising the whole of that subject"—(Letter of Sir Fitzroy Kelly to Lord Brougham). The result of consolidation will be, that 40 vols. of statutes will be reduced to 4, which will constitute the statutes at large, and contain the whole of the acts in actual force, arranged and digested, so that an inquirer may find at once all the statute-law upon any particular subject.

Jurisprudence.

courts of justice, would be regularly obtained by the legislature. It has also been suggested that there should be a commission for receiving complaints against the law. Cases of hardship constantly occur that never enter courts of justice; and defects in the law are daily suggested to advocates in private practice, by cases neither in court nor in hand, which they forget in the hurry of business, but which might be made available for law reform if there was a commission to which they might be notified. The preparation of the materials thus collected for the code should be the work of sub-departments of the legislature, which, over and above its other duties, should be able to keep the laws parallel with judicial legislation. As to the third requisite, it has been suggested that there should be a standing commission to publish the acts of the legislature, and classify and adapt them for introduction into the divisions of the code, which it should be their duty also to re-edit at certain intervals, probably of from three to five years, according to the scheme of Lord Bacon. The code would thus never be long in the rear of the current legislation; and the law, logically arranged and authenticated by the state, would be always accessible and certain. It is unnecessary to do more than

mention here the necessity of accommodating the language of the code to that of the people. It is important that it should be plainly written in the tone of the time. But as the growth of language is slow, the necessity of altering the code on this account would be felt only at long intervals.

When the code is equipped with the provisions above suggested, judicial decisions will be of value, as containing its interpretation and the history of its application, and exemplifications of its failure and success. They will, in consequence, continue to be studied by lawyers, and become of importance to legislators. The reform which we have been contemplating, when effected, will no doubt be accompanied with provisions for authenticating reports of decisions, and keeping under their number, by restricting them to crucial and leading cases, and throwing overboard the reports of repetitions of decisions which now swell the records. The mass of the decisions thereby becoming manageable, they would reward careful study. The auxiliary law-literature founded on their analysis would thenceforth be rather critical than expository,—aiming at the improvement, instead of the illustration of law; undermining its authority no longer, save by examining and testing its principles.

Jurisprudence.

PART IV.—JURISPRUDENCE.

Jurisprudence, or the doctrine of the application of law, accepts law as it is, and considers how its operation may be made most effectual. While this is its peculiar province, it is strictly not a separate doctrine, but falls under the general theory of legislation. Rules of law, and the manner of prescribing and enforcing them, cannot well be altogether separately considered, and are here separately treated of chiefly for the convenient discussion of the various questions concerning law.

To protect rights is the same thing as to apply law. Law commands certain actions to be done, and permits or forbids others. All its rules and institutions, whether relating to persons or things, are, directly or indirectly, limitations or definitions of powers of action, assigned by it, and vested in, particular persons, over the persons of others or things. And since these powers of action are rights, it follows that to protect rights is to apply law.

As every power given to one over others or over things limits the powers of others over themselves or over things, law, in conferring rights which, as enjoyments, are objects of desire, necessarily creates obligations proportionally burdensome, and therefore objects of aversion. Rights, therefore, are exposed to be contested and violated, and need to be protected, both to secure their possession to those to whom the law has assigned them, or in whom it has vested them, and to prevent their violation. The object of inquiry is the best means of affording them this double protection.

The definition of rights as a means of protecting them.

In the first place, rights must be clearly defined. Their definitions, by setting forth the extent of the powers which they imply, and the facts which vest them in particular persons and terminate their possession of them, will prevent disputes as to their ownership, while warning men off from interfering with their exercise. It is only when it is certain what rights are, and who owns them, that public opinion and the other sanctions of law can operate steadily in their defence. For similar reasons, offences, or violations of rights, must also be clearly defined. Their definitions will at once warn men off from committing them, and steadily direct the unfavourable sentiments of men against those who commit them.

Divisions of jurisprudence.

It is farther necessary, for the protection of rights, to provide (1), for the settlement of disputes, as to their extent and possession, and (2), for guarding them from violation, and for the prosecution and punishment of those who violate them. It is designed to take up, under the title "Judicial

Procedure," the consideration of the provisions to be made for the settlement of such disputes and the prosecution of offenders; and under the title "The Doctrine of Punishments," that of the leading questions connected with the prevention of offences and the punishment of offenders.

I. The nature of the judicature, and the procedure before it, must depend on the nature of the cases which give rise to legal contests, and the operations necessary for their settlement. Causes of litigation may be complicated in various ways. Civil causes may involve several questions of right, each of which may require separate settlement, or two or more of which may rest on the same grounds, and may be settled conjointly; and they may include several persons as litigants for their joint or individual interests. But the most complex cause of this sort is resolvable into simple causes, in which single rights and pairs of litigants are concerned. Criminal causes also may be complicated so as to involve several persons as accusers and defenders, and several charges, and are similarly resolvable into simple causes with single charges and pairs of litigants; so that all causes are representable by the two cases of A and B disputing about a right, and of A complaining that B has violated a right. What has to be done in either case, the law being clear and settled, is to solve a question of fact. In the former case, In whose favour, A's or B's, is the fact on which the legal title to the disputed right depends?—in the latter, Did B commit the act charged upon him by A? This question of fact is the issue of the case between A and B, and in a criminal cause, appears at once from the complaint; but in a civil, it is to be derived from the whole circumstances founded on. The first operation to be performed, then, is that necessary for bringing the case to an issue in point of fact. The issue being obtained, the next operation is to lead and weigh evidence to settle the question of fact. The fact being ascertained, it remains to declare its legal consequences. This is the decision of the case to be followed by warrant to the executive to enforce its terms. If the fact favours A, the decision is that the disputed right is his; if B committed the act charged on him, the decision is that he shall suffer the consequences attached to it by law. Here the distinction between the two cases may be dropped, as the latter plainly does not require a different procedure from the former. It is a simple case of the former, in which the operation to get at the issue is unnecessary. We may now consider the case of A and B disputing about a right, assured that all necessary to be done in the most complex cause will

Jurisprudence. appear from the consideration of the procedure necessary in that case.

The three operations to be performed, then, are,—1st. To bring the dispute between A and B to an issue in fact, in which A shall affirm and B deny that something happened or was done in a particular way. 2d. To lead proof as to the fact. 3d. To pronounce judgment and issue warrant for execution. As the conditions of successfully performing the second operation have been discussed elsewhere in this work (see art. EVIDENCE); and as there is nothing to be said about the third, the business in hand is wholly with the procedure for evolving issues, the constitution of the judicature for the several operations, and the provisions to be made for the fidelity and fitness of judges.

Preparation for proof. A and B dispute about a right to which each believes himself entitled because of certain actual or supposed facts which he conceives to have so happened as to have made it his. Now, the facts which invest rights in particular persons, and divest them of them, being defined by law, what in the first place is necessary is, that they come together before a person who knows the law, and can tell them the legal qualities of the facts on which they rely. Suppose the suit to be at the instance of A, he must, to commence, state before this person the fact on which he relies. B may then deny it or its investitive quality, or allege a subsequent fact vesting the right in himself, or an antecedent fact preventing that alleged by A operating to vest it in him. If B admits A's allegation, but denies the investitive quality of the fact, the judge has merely to declare whether it has that quality or not. If he admits its quality, but denies that it happened as alleged, the issue is at once reached whether the fact happened as alleged? If, admitting the fact and its quality, B alleges a subsequent or antecedent fact, vesting the right in himself, or preventing it vesting in A, the same course is open to A with respect to B's allegation, that was open to B in respect of A's first allegation. He may deny it; admit it and deny its quality; or allege an antecedent or subsequent fact, as in the former case. At every stage there thus arises a question of law or fact, or both; and after a few steps at farthest, if the parties are made to face each other, the issue or final question of fact is naturally evolved, and the case prepared for proof.

The allegations of A and B, in turn meeting one another, soon exhaust the whole circumstances founded on. The issue will be the more speedily and correctly evolved, the fewer fictitious circumstances introduced to complicate the case. It is desirable, then, that neither party make any allegation that is not true; and that the facts alleged should have the qualities ascribed to them. To secure the first, litigants should be subjected to certain penalties if convicted of making allegations that they knew to be false; *e.g.*, they should be made to bear the expenses of the suit, so far as due to its being complicated by these allegations, and farther, a pecuniary fine, to be fixed according to the circumstances. It has also been proposed that they should be made to swear that their allegations are true to the best of their belief, and thus to make them under the penalties of witnesses. There appears to be no good reason why this should not be done; and there certainly is good reason why something should be done to obviate the evils of litigation as at present everywhere conducted, owing to the moral turpitude of suitors, who are unfortunately kept in countenance by the traditional morality of the bar. To secure the second desideratum, it is sufficient that the allegations be made before a judge acquainted with the legal qualities of facts, and who can at once pronounce whether they have those ascribed to them. Also, the convenience of the judicature, and the interests of justice require, that at this stage, in all but the simplest cases, advocates acquainted with the law, and accustomed to deal with complex facts, should be interposed between

Jurisprudence. suitors and the judicature; that the facts of cases may be set forth in continuous chains, and not in ravelled wisps; and that cases be simplified before entering court, by being stripped of all matters plainly irrelevant. The presence of advocates is, farther, a security for the judge's attention to matters which, if set forth by suitors themselves, might be underestimated or overlooked.

If the judge knows the law, and has the requisite power of attention, he is more likely to manage this part of the business with fidelity and efficiency, singly, than with co-adjutors sharing the responsibility of the task with him.

It appears that a single judge is the only agency required for the preparation of the case for proof. On the operation of leading proof, the reader may consult the articles on EVIDENCE, and TRIAL BY JURY. There appears to be little room for doubting that a single person of probity and ability, accustomed to taking and weighing evidence, is more likely to settle the question of fact satisfactorily than several persons, selected almost at random, as a jury, and unaccustomed to these operations. The question is between the value of the vague impression from the evidence received by these men, and that of the logical inference from it of an acute mind alive to all the little circumstances which affect the credibility of witnesses, and accustomed to compare evidence of different sorts, and sift contradictory evidence. As in the first operation, too, the responsibility of the task is greatest when resting on a single person. Since there is nothing in the third operation requiring more than one person for its performance, it appears that a single judge is the only agency required for all the three stages of judicial procedure.

It is unnecessary to enter particularly here into the provisions requisite to secure the fidelity of judges. Most of them must be inferred from the general provisions against offences to be hereafter discussed. Those at the head of the government must be guided by public opinion, in a large measure, in making appointments to the judicial seat. For the rest, the publicity of the judge's proceedings, and, particularly, the fact of their taking place before an audience of lawyers interested in his honestly discharging the judicial function, are among the best securities for his attention and rectitude. To this we add, the right of appealing against his judgment to a superior tribunal, as a great security against his negligence and unfairness. This right should be given to suitors in all cases in inferior tribunals. No reason can be assigned why it should be given in one case and not in another. The only consequence of giving it in all would be a necessity for a greater number of courts of appeal; but as there is no good reason why the judge on appeal should not be single, the number of superior judges required would probably not be greater than at present, on the system of divided responsibility. The appeal, also, might be simplified by the judgment in the superior courts proceeding on an authentic record of the proceedings in the inferior.

II. It must now be inquired how undisputed rights may best be guarded from violation, and how persons convicted of violating them should be dealt with. Though all wilful violations of rights come under the generic name of wrongs, only certain of those made penal are called crimes; yet it will be convenient to speak here indifferently of all acts to be prevented as crimes.

In inquiring how crimes are to be prevented, attention must, first of all, be given to their causes. The cause of every crime is the desire of some actual or imaginary good. A man is led to steal by the desire of property, and to injure another's person by resentment. Generally, the desires which cause crimes are the same that lead to other and necessary forms of human activity. And as they are essential to man's existence, the question is, What obstacles must be devised to prevent their leading to criminal acts, while leaving them free within legitimate limits?

Jurisprudence.

How they are to be counteracted.

The principle on which acts are to be selected for punishment.

Natural obstacles to crimes.

They lead to crimes unless they are counteracted by stronger motives, or the criminal acts are prevented by the interposition of physical force. It is clear that crimes cannot be prevented in more than a few cases by physical force. They must be prevented, then, by supplying motives to counteract the desires which lead to them; and, considering what these are, the counteracting motives must be desires for greater advantages than those obtainable by the criminal acts, or aversions to evils certain or likely to follow upon their commission. To supply motives of the former class would be to reward men for not committing crimes, and is wholly out of the question. It remains that the motives to crimes are to be counteracted by applying evil consequences to their commission.

But it is expedient that no evil be produced that does not, directly or indirectly, produce a greater good. This is the principle on which injurious acts are to be selected for prohibition in the penal code; and in applying it, regard must be had to all the consequences of making acts penal through which the influence of the penalties is diffused through society. The immediate consequences of making failure to pay a debt penal might be beneficial, but its consequences in the long run on trade and commerce would certainly be mischievous. One deduction from this principle is, that the protection of rights should be left to the fear of the direct evil consequences of violating them, whenever it is ordinarily sufficient to prevent their violation. Another obvious deduction is, that penalties should be annexed to no acts, the commission of which they are unsuited to prevent.

The direct evil consequences of injurious acts are the natural protections of the corresponding rights; they are obstacles to crime, existing in the nature of society and of man, which it is the duty of the legislature to uphold and strengthen. They either depend on the moral sensibilities of men, or on the immediate practical results of provoking their unfavourable sentiments. Over the area of the common experience that the largest measure of durable good is attainable only in the way of justice, the desires of individuals for happiness concurrently constitute an instinct in society of self-preservation from all who practice injustice, which not only secures that they shall be punished with odium in proportion to their sensibilities and the public estimate of their deserts, but that, when hardened to shame, they shall be ruined and cast out of society. The task of the legislator, so far, must be, to enlighten men's moral judgments, and stimulate and tutor their unfavourable sentiments by promulgating just views of criminality. But, further, he must take care that the unequal development of society shall nowhere efface or prevent the effects of those impressions of mutual hatred and esteem on which the moral tone of the community depends. Accordingly, wherever peculiarities of experience have generated false sentiments, that shelter one class of society from the indignation of the rest, it becomes the duty of the legislator to educate and reform that class, and to check the causes of vagabond and criminal habits which perpetuate the families of the morally obtuse. So far as religion constitutes a more awful morality, with more terrible, if less immediately obtrusive penalties, it is the duty of the legislator to foster a universal regard for its sanctions, and to cherish the general diffusion of its principles.

It will never be possible, however, so to train or elevate all that they shall feel the force of these natural obstacles, which also must often fail by defeating themselves. The aspiring classes, in all ranks, are particularly exposed to an unfavourable action of public opinion, being tempted, on their fortunes changing, to continue their upward progress by the secret avenues of fraud, lest they should appear ridiculous in suddenly descending from positions honestly attained. Also, so long as criminals can evade the natural

consequences of their crimes by shifting their localities, there must be other means of preventing crimes. Without indorsing the opinion that men are to be held in awe by the terror of physical pain alone, it will always be necessary to employ motives from the physical source to counterbalance the effects of the dissocial passions.

The evils incurred by transgressing the natural obstacles are due to the incongruity of crimes to the constitution of society. By increasing them ever so much no evil uncompensated for by a greater good can be produced; because they can only be increased by transfusing society with the sentiments essential to its well-being and stability—increasing the vigour of its system, so as more speedily to reject whatever is noxious to it; and because, as the evils increase, the occasions become less frequent of their being inflicted, from the diminution of the criminally disposed and greater efficacy of the obstacles. The evils incurred by transgressing the artificial obstacles, on the other hand, are created by the legislator, and are pure evils, unless they are successfully employed to prevent greater. His design, then, must be to prevent crimes by *threatening* to inflict these evils. When his threats do not prevent crimes, and the evils have to be actually inflicted, his design has failed. They are then to be inflicted to maintain the future efficacy of his threats.

According to this design, the first condition of the employment of punishments is, that they must be fixed and declared by law, so as to be standing menaces against the criminally disposed. The second condition depends on its being more desirable to prevent the more than the less mischievous crimes, and is, that the penalties declared by the law must be graduated to the scale of crimes, the former ascending in severity as the latter ascend in mischievousness. For, if the same penalty were threatened against crimes of different degrees of mischievousness, there would be nothing to deter a man from committing the more mischievous as often as it promised to be the more profitable.

Besides the principle of proportioning penalties to the mischievousness of crimes, none other is practically applicable; it is the single principle on which the relative severity of the punishments in different cases must depend. This will appear from a brief view of the only other principles that have ever pretended to determine penalties. It is out of the question proportioning punishment to the moral guilt or to the criminal intention of offenders; for, as the former is held to diminish as temptation increases, penalties on that principle should be least when, for the purpose of prevention, they should be greatest; and because it is impossible to measure the latter so as to proportion punishment to it. Nor can the principle be that of proportioning punishments to the motives which lead to crimes; because (1), there can be no measure of motives; and (2), even if motives could be measured, they would be no measures of the punishments sufficient to counteract them by producing fear. Motives to crimes rise from the concurrence of desirableness in objects obtainable by them with circumstances which diminish the difficulties and risks of committing them, and depend on the views taken by criminals of the whole circumstances under which they are committed. It is impossible to estimate either of these factors in motives as seen from the stand-point of criminals, far less the motives, as determined by their concurrence. This, even when the object has a market-value; but when it is the gratification of a sense, or passion, the estimate is wholly impossible. And even if we could appreciate motives, yet, since punishments cannot be made to follow immediately on crimes, and the causes by which they lose deterring force are beyond our cognizance, our measures of motives would be no guides in annexing penalties. The fear of punishment felt by a criminal, supposing him to deliberate, depends largely on his imagination and a calculation of chances based on his pre-

Jurisprudence.

Jurisprudence.

vious experience and immediate means of concealment. An error in reasoning, or in the calculation of a probability, may take all the terror from the law. Also, in the majority of cases, the motives to crimes are wholly vague—as when a man breaks open a till or into a house. In fact, to apply this principle, the law, instead of aiming at generality, would have to address itself to each individual criminal, and punish him on an appreciation of the whole circumstances under which his crime was committed. But this would be to break through the first condition of the employment of punishments, and, leaving penalties to be determined by judges, leave to their discretion what laws, if any, should be enforced. It remains that penalties be proportioned to the mischievousness of offences.

Comparison of crimes in point of mischievousness.

It would be difficult to compare crimes in point of mischievousness were not incomparably their worst evil the feeling of insecurity which they produce; but by attending to this single effect of crimes exclusively, an approximate measure of their comparative mischievousness may be obtained. It would again be difficult to make direct appreciations of the extent of diffusion and degree of intensity of this feeling in different cases; but their measures may be indirectly obtained by comparing—1, The importance of the rights violated in different cases; 2, The difficulties of individuals guarding themselves from similar acts; and, 3, The spheres of operation of the desires leading to crimes of different sorts. In this way treason, putting the lives and property of all in danger, takes its place at the top of the scale; while petty thefts, causing little more than annoyance to the persons whose property is stolen, and exciting, when frequent, only the feeling of the necessity of greater care in storing things, take their place at the bottom. Between these all crimes whatever may readily be arranged. To compare theft, robbery, and burglary, for instance:—Thefts make property insecure, but raise no sense of personal danger; robberies, when frequent, add personal insecurity in going abroad to insecurity of property; to which burglaries, when frequent, add insecurity in staying at home. Again, supposing the motive, *i.e.*, so far as concerns the desirableness of the objects of the acts, in the three cases to be the same:—Theft waits opportunity; robbery makes opportunities; and burglary makes opportunities in defiance of all the ordinary protections of person and property. Murder for money, again, is more mischievous than when committed in the heat of passion. Passion is accidental between the criminal and his victim; but all desire money, and all who have it feel exposed to be murdered for it. While the mischievousness of crimes may be compared in this way, it is impossible to estimate precisely their differences in degrees of mischievousness. Beyond saying that in one case punishment should be greater than in another, theory can give the legislator no practical guidance; so that a large amount of arbitrariness must be admitted into this branch of law.

The doctrine of satisfaction.

So far we have seen how penalties are to be proportioned to crimes, but not how their sufficiency for the purpose of prevention is to be secured. Perhaps the nearest approach that could be made to securing their sufficiency would be to make part of the punishment, in every case in which it is practicable, consist in the criminal repairing the injury occasioned by his criminal act. When the injury is done to property or reputation, it may, in most cases, be repaired; and even when it is done to the person, a substitute for reparation may in many cases be exacted. Stretched to its full extent, the doctrine of satisfaction would require that the criminal should not only be made to compensate the person injured by his act, but to defray by his labour, or from his estate, the expenses of convicting and punishing him. But the extent to which the principle should be applied must be determined by expediency in the circumstances of cases.

Jurisprudence.

It remains to set forth the penalties available from the physical source, and the qualities which lots of punishment should have for the purposes of prevention. A man may be punished through his person directly—(1), by being subjected to bodily pain, or (2), to hard labour; and (3), by being deprived of his liberty; and, indirectly (4), by being deprived of his property. The punishments which he may be made to suffer in these ways may be made to vary—(1), between scourging and death; (2), between a brief term of hard labour and perpetual slavery; (3), between imprisonment for a brief term and for his natural life; (4), between a small fine and his whole fortune. Also, these punishments may be made up in an indefinite number of lots, by combining different degrees of the various sorts, so as to be of every degree of formidableness.

It appears, then, that these penalties possess the two Primary qualities most essential to punishment, *viz.*, formidableness and measureableness, so that they may be formed in lots increasing in severity with the classes of crimes which they are designed to prevent. The other qualities which a lot of punishment should have for the purpose of prevention are obvious. 1. It should be suggestive of the crime to which it is attached, that the idea of it may be closely associated with that of the crime. 2. It should be calculated to operate with the same intensity on all persons. 3. It should be disabling, *i.e.*, such as to prevent the criminal doing further injury to society.

Secondary to these qualities are others which a lot of Their punishment should have in the view of benevolence, and which bear only indirectly on the prevention of crime. 1. It ought to be humane, *i.e.*, occasion as little as possible useless suffering. 2. Corrective, tending to the moral improvement of the criminal. 3. Remediable, in case it should be discovered to have been undeserved. It must not be attempted, however, to give it these qualities at the expense of its formidableness, which benevolence indeed requires it to have, that the fear of it may prevent the necessity of inflicting it. Its sufficiency to prevent crime is what must chiefly be attended to. This, however, depends not wholly on its severity, but on the degree of expectation that it will be inflicted. The more severe the penalty is, this expectation being the same, the greater will be its deterring force; but, the penalty being the same, the less this expectation, the less effectual will the penalty be. Also, if its infliction is certain to be long delayed, it loses force, through the operation of psychological laws too well known to require explication here. So that the certainty of punishments being speedily inflicted is, it may be, of as great importance as their severity in determining their sufficiency. They may, accordingly, be made less severe in proportion as they are made proximate and certain.

Here must be noticed the fact, that a limit is set in the nature of things to the advantages, in a jurisprudential view, derivable from severe punishments, as their severity tends to diminish their certainty, through men's reluctance to cause others to suffer great pains. The more severe punishments are the more likely they are to be effective; but then, the more severe, the less likely they are to be inflicted; and the point is reached where what is gained by increase of severity is lost by increase of impunity. It is all the less necessary, too, that punishments should be severe, that one of their chief functions is to direct public disapprobation against offenders. It is due to their discharge of this function, that in countries remarkable for lenient penal laws, crime is as effectively prevented as in others where they are very severe.

It is probable that, when all has been done to secure the certainty and proximity of punishments, they may with safety be made exceedingly lenient. Among the means that may be employed to secure these are—1, The establishment of a vigilant police, to secure the speedy detection

Jurisprudence.

tion of criminals; 2, Of a system of public prosecutors, and of courts in which criminals may be tried without delay, to secure their speedy conviction; 3, Restriction of the Judge's discretion by defining the circumstances which may justify him in lightening punishments, among which should not be the plea of a "first offence," for which a first conviction is too often mistaken; 4, Restriction of the pleas on which punishments may be evaded,—when the plea is insanity, confinement in a public asylum should follow; 5, The full infliction in all cases of the penalties incurred by criminals. Let the law have rules for singular cases; but let its awards be in all cases definite, and certain to be inflicted. Such a practice as that recently adopted in this country of commuting punishments, and of giving criminals the chance of winning off parts of the penalties incurred by them, is contrary to the first principles of jurisprudence; and the only apology that can be made for it is that it originated in a desire to remedy the evils of a penal system far too severe.

Next to being made formidable by the concurrence of severity and certainty, it is important that punishments should be made equable. The more equable they can be made, plainly over the wider area will their deterring force be exerted. It is extremely difficult, however, owing to the varieties of complexion and condition presented by men in society, to give penalties any great degree of this quality. The same pecuniary fine may deprive a poor man of his whole fortune, and be no more to a rich one than he daily spends in pleasure. Imprisonment may be fatal to the prospects of a man in a middle station, while to the peasant, who, on the approach of winter, considers whether to retire to the union or the jail, so far from being a punishment, it is a favour. Hard labour is severe on men unaccustomed to it, but the ordinary fare of multitudes; and even transportation, a grievous calamity to some, is welcomed by others. It has been proposed that, to secure a high degree of this quality, a discretion should be given to judges to apportion punishments to the nature and condition of offenders. But, besides that it would be difficult for judges correctly to appreciate these, it would be contrary to the first condition of employing punishments to leave such a discretion with them.

Connected with the difficulty of making punishments equable is that of making them equally severe for the same crimes, even when, nominally, they are the same. It is simply impossible to attain equal severity in the same punishments inflicted in different places on different persons. Their severity in the last resort depends partly on governors of jails, but principally on turnkeys,—on coarse people and coarse machinery. The machines made to equalize punishments have failed; nor, had they succeeded on their part, would they have brought us near the equality which benevolence desiderates, and which could only be reached by punishing men proportionally to their sensitiveness and strength. The treadmill, Sir George Grey's crank, and other machines, are found to vary, as far as to require, in some cases, three times the labour per day necessary in others. When the crank is adjusted to require a few pounds force, it depends on the turnkey's care in oiling it whether it may not require several hundred. The differences also between criminals in point of skill and strength make it impossible to equalize punishments by prescribing the same amount of work to be done by different persons. All that can be effected is a rough approach to equality. The inequalities remaining must be borne as accidents of the system which the legislator is constrained to employ; they are in many cases compensated by its other accidents, and, at any rate, are as nothing to the whole consequences of crimes to convicts.

The most grievous part of punishment is, in many cases, its effect on the convict's relation to society, to which is partly due what truth there is in the saying, "Once a criminal,

always a criminal." The question, whether anything should be done by the legislator to save convicts from the social consequences of crimes, is a difficult one. The answer to it must depend on that to another, What would the effect of doing so be as regards the prevention of crimes? The reaction of society upon criminals leads them to war against it, and back to the dock; so that while the fear of it tends to prevent crime, itself tends to occasion it. This reaction cannot, however, be prevented; nor would it be desirable to prevent it, seeing that it acts to deter almost all from crime, and to propel to it only the few who have offended. Criminals cannot, then, be thrown back on society, and, at the same time, saved from the social consequences of their crimes. They can only be saved from them by being retained under the care of the state. But to save them in this way would be to let them drop out of society, and to extinguish all the minor differences of penalties, which would have no proportion to this single result of crimes. It would be as if there was the same penalty for all crimes which provoked this reaction, and no means of preventing men from committing the more mischievous as often as it promised to be the more profitable. And this argument will hold good till provisions are made for the gradual ascent into society of those who incur its decided enmity. As yet it is impossible to say whether such provisions can ever be made, or to pronounce on the propriety of attempting to make them. We desiderate a scientific analysis of full criminal statistics; and till that has been procured, these, and other questions concerning the treatment of convicts, must remain unsolved. At present the case of a criminal at war with society is as melancholy as it is helpless. Whatever private individuals may do to improve it, it seems contrary to principle that the legislator should interfere in such work. His business, on the contrary, must be to sharpen, by every means in his power, and guide the social instinct to which the position is due. And by such means, so far as yet appears, he will, in the long run, do most for the prevention of crimes.

The importance of correct information regarding the Criminal operation of penal laws is universally recognised; criminal statistics, when properly collected and interpreted, disclose the causes of crime, its progress, and the defects of the agencies for repressing it. But on none of these points can even an approximate conclusion be drawn from criminal statistics as at present collected; their *prima facie* evidence must be received with large reservation. And, for two reasons, the statistics of crime in Scotland should be selected as the basis of an explanation of the nature of these reservations; first, because of the smallness of its area and population, and next, because its agencies for the prosecution of offenders are more definite than those of England.

The only point that can here be touched upon respects the evidence of our criminal statistics as to the progress of crime. The statistics of crime in Scotland bearing on this point are confined to the numbers of commitments for trial and of convictions; and arguments on its progress proceed on comparisons of the commitments in different years. It would appear, at first sight, that the main body of crime in each year might safely be averaged to its number of commitments. But unless we know that the causes which affect commitments remain invariable over the years to be compared, we can have no security that this average may not be wholly erroneous. The importance of attending to the causes which affect the administration of justice is indicated by the striking variations in the differences between commitments and convictions in different years. Thus, out of 4027 commitments in 1852, were obtained only 3018 convictions, leaving 1009 crimes unaccounted for; while, out of 3019 in 1853, were obtained 2849 convictions, leaving only 260. And equally striking variations are presented in the differences between commitments and convictions in

Jurisprudence.

Jurisprudence.

other years. To explain these variations, we should be able to point out the causes which make the zeal of the police and of procurators-fiscal for the prosecution of offenders, to exceed their care in preparing cases, and *vice versa*. Looking to the years 1852 and 1853, for example, it may have been that the fall of 1008 commitments for trial, and the disproportioned diminution of the difference between commitments and convictions, were due to the experience, in the former year, of the inutility of sending to trial cases in which convictions were not certain to be obtained. So far from crime being less in 1853 than in 1852, in the proportion of 4027 to 3019, it may have continued the same over the two years; and the convictions in the latter differ from those in the former by 169 only. But the strongest reason against arguing without reservation on the progress of crime from commitments for trial, lies in the returns made by the crown agent of undetected "housebreakings and other depredations on property," in 1854-55, which demonstrate that the main body of crime has hitherto always lain concealed. When corrected, by adding to them proportional numbers for the places from which no returns were made, they show that, in that year, the *whole* number of serious offences against property was, at least, more than eight times the convictions for such offences, and that the undetected crimes alone were more than quadruple the commitments. How these proportions may vary from year to year, is beyond our cognizance; but it is proved that the main body of crime is so great in proportion to the commitments, that the latter may be varied indefinitely from year to year by causes which affect them, without any corresponding variations necessarily taking place in the main body of crime. The limits of variation of commitments are so wide short of exhausting crime, that no inference can reasonably be drawn from them as to its progress. This will farther appear, if attention is given to the commitments for trial during the last twenty years, and to the variations in the principal causes affecting them that have occurred in that interval, viz., in the police force and constabulary, and the system of procurators-fiscal. Commitments took a start in 1841, the average for the years 1841-45 being 347 above that for the years 1836-40. They again took a start in 1846, the average

for the years 1845-50 being 792 above the average for 1840-45; and, since 1850, the average has been lowering. Now, it is noticeable that 1840 is the date of the act empowering the establishment of the county constabulary, which attained its highest degree of efficiency about 1846; and that the zeal of a large batch of procurators-fiscal for the prosecution of offenders was cooled in 1850 by their being put upon fixed salaries. Who will undertake to say how far these circumstances have had to do with the apparent advance and retrogression of crime? And till we can say how changes in the prosecuting agencies affect the commitments, they are valueless as indications of its progress. In fact, criminal statistics, as at present collected, give us, in commitments for trial, convictions, and prison statistics, measures not of crime but of the pressure upon it, of the state machinery for repressing it; and in order to get from them approximate measures of the variations in crime itself, we should be able to modify them by adding to or subtracting from them such numbers as may represent the effects of such variations as take place in that machinery. And in attempting to interpret them when thus modified, to ascertain from them whether crime is advancing or retrograding, the manner in which crime and the state machinery act and react on one another should not be lost sight of. A downward tendency in the commitments, so far as due to the impaired efficiency of that machinery, must be attended by an upward tendency in crime through the increase of impunity, and *vice versa*. So that the true conclusion as to the progress of crime *may* be the opposite of that which even the corrected statistics are, on a first view, calculated to suggest. And this holds, notwithstanding that an upward tendency in crime must be accompanied by a tendency towards improvement in the state machinery for repressing it through the increase of the feeling of insecurity. For the impression of impunity affects crime more rapidly than the sense of insecurity affects the agencies for repressing it. The former, as it were, affects criminals individually and at once; but the latter, notwithstanding the sensitiveness of modern society, must acquire a considerable degree of intensity, and be felt for a considerable time before it can effect changes in the state machinery. (J.F.M'L.)

Jurisprudence.

LAW OF NATIONS.

I.—*Ideas involved in the term Law.—These ideas how modified in the term Law of Nations.—The only sanction applicable to the Law of Nations is the popular sanction.—What dependence may be placed upon the popular sanction.*

IN the meaning of the word Law, three principal ideas are involved; that of a command, that of a sanction, and that of the authority from which the command proceeds.

Every law imports that something is to be done, or to be left undone.

But a command is impotent, unless there is the power of enforcing it. The power of enforcing a command is the power of inflicting penalties if the command is not obeyed. And the applicability of the penalties constitutes the sanction.

There is more difficulty in conveying an exact conception of the authority which is necessary to give existence to a law. It is evident that it is not every command, enforced by penalties, to which we should extend such a title. A law is not confined to a single act; it embraces a class of acts: it is not confined to the acts of one man; it embraces those of a community of men. And the authority from which it emanates must be an authority which that community are in the habit of obeying. An autho-

riety to which only a temporary obedience is paid, does not come up to the notion of that authority which is requisite to give existence to laws; for thus the commands of a hostile army, committing plunder, would be laws.

The conditions which we have thus described may all be visibly traced in the laws which governments lay down for the communities to which they belong. There we observe *the command*, there *the punishment* prescribed for its violation, and there *the commanding authority* to which obedience is habitually paid.

Of these conditions, how many can be said to belong to any thing included under the term Law of Nations?

By that term is understood, something which either does, or which, it is supposed, ought to bind the conduct of one nation towards another.

But it is not understood that one nation has a right to command another. When one nation can be commanded by another, it is dependent upon that other; and the laws of dependence are different from those which we are at present considering. An independent nation would resent, instead of obeying, a command delivered to it by another. Neither can it properly be said that nations, taken aggregately, prescribe those laws to one another severally; for when did they ever combine in any such prescription? When did they ever combine to vindicate the violations of

Law of Nations.

them? It is therefore clear, that the term command cannot be applied, at least in the ordinary sense, to the laws of nations.

In the next place, it would not seem that any thing deserving the name of sanction belongs to them. Sanction, we have already seen, is punishment. Suppose nations to threaten one another with punishment, for the violation of any thing understood to be a law of nations. To punish implies superiority of strength. For the strong, therefore, the law of nations may perhaps have a sanction as against the weak. But what can it have as against the strong? Is it the strong, however, or is it the weak, by whom it is most liable to be violated? The answer is obvious and undeniable. As against those from whom almost solely any violation of the laws of nations need be apprehended, there appears, therefore, to be no sanction at all.

If it be said that several nations may combine to give it a sanction in favour of the weak, we might, for a practical answer, appeal to experience. Has it been done? Have nations in reality combined, so constantly and steadily, in favour of the law of nations, as to create, by the certainty of punishment, an overpowering motive to unjust powers, to abstain from its violation? For, as the laws against murder would have no efficacy if the punishment prescribed were not applied once in fifty or a hundred times, so the penalty against the violations of the law of nations can have no efficacy if it is applied unsteadily and rarely.

On the mode in which it has been applied, we may appeal to a great authority. Montesquieu says, "Le droit public est plus connu en Europe qu'en Asie : cependant on peut dire que les passions des princes, la patience des peuples, la flatterie des écrivains, en ont corrompu tous les principes. Ce droit, tel qu'il est aujourd'hui, est une science qui apprend aux princes jusqu'à quel point ils peuvent violer la justice, sans choquer leurs intérêts." (*Lettres Persanes*, xciv.)

To go a little deeper, we may consider whether the interest of nations, that which in the long run governs them all, can ever produce combinations, from which an effectual sanction, of the nature in question, can be expected to proceed. That they would derive some advantage from the general observation of those maxims which have been called laws of nations, frivolous as are the points upon which the greater part of them turn, cannot be denied. These advantages, however, are seen at a distance, and with the mind's eye; they are speculative rather than sensible. The inconveniences, on the other hand, which must result from any movement to lend effect to the law of nations, are immediate and formidable; the whole train of the evils of war are almost sure to arise from them. The latter class of impressions must, in general, be far more powerful than the former; and thus the interposition in favour of the law of nations will generally be shunned. A nation is often but too easily stimulated to make war in resentment of injuries done to itself. But it looks with too much coolness upon the injuries done to other nations, to incur the chance of any great inconvenience for the redress of them.

Besides, the object is to be gained by the means of combination. But the combinations of nations are very difficult things. Nations hardly ever combine without quarrelling.

Again, all nations ought to combine for an object common to all. But for all nations to combine in any one enterprise is impossible. Suppose a prince to have violated the law of nations, it would be absurd to suppose that all the countries on earth should conspire to punish him. But if not all, what is to be the selection? Who shall come forward; who stand excused? By those who are condemned to the sacrifice, in what proportion are the con-

Law of Nations.

tributions to be made? Who is to afford the greatest, and who may come with the least?

It is unnecessary to pursue any farther the analysis of this extraordinary hypothesis. It is evident, from what has been said, that it is full of impracticabilities.

Are we, then, obliged to consider the maxims or rules which pass under the name of Laws of Nations, as utterly without force and influence; and the discourse which is made about them as mere affectation and impertinence?

Not wholly so. It is of use that the ordinary intercourse of nations should be conducted according to certain forms, generally known and approved; because they will be observed on all occasions when there is no particular motive to violate them, and will often prevent disputes which might arise on frivolous occasions. They resemble in this respect the ceremonial of a court, or the established forms of polished society.

The objects, however, which are understood to be embraced by the law of nations, are of two sorts. The first are those minor objects which partake more of form than of substance; the other are objects which deeply affect humanity. That there are certain interests of nations, which it were good to have considered as their rights, and of which it is infinitely to be desired that the violation could be prevented, is most true. But if national law has no penalty annexed to it; if the weaker party who is wronged has no means of redress, where, it may be said, is the advantage of such a law? Or where the propriety of calling that a law which is only a declaration respecting rights; violated by the more powerful party with impunity, as often, and to as great an extent, as he pleases?

There is still, however, a power which, though it be not the physical force either of one state or of a combination of states, applied to vindicate a violation of the law of nations, is not without a great sway in human affairs; and which, as it is very nearly the whole of the power which can be applied to secure the observation of that law, deserves to be carefully considered, that, by duly appreciating its efficacy in this important affair, we may neither trust to it where it will disappoint our expectation, nor neglect the use of it where it may be turned to advantage.

That the human mind is powerfully acted upon by the approbation or disapprobation, by the praise or blame, the contempt and hatred, or the love and admiration, of the rest of mankind, is a matter of fact, which, however it may be accounted for, is beyond the limits of dispute. Over the whole field of morality, with the exception of that narrow part which is protected by penal laws, it is the only power which binds to good conduct, and renders man agreeable and useful to man. It is evident, also, that where there is not great inequality, it is a power, the binding force of which must be necessarily great; because every individual, considered in himself, is weak and helpless as compared with the rest of the community. Unless, therefore, he can prevail upon them to abstain from injuring him, he must be exposed to unlimited suffering. And if, on the other hand, he can prevail upon them to combine in doing, or in desiring to do, him good, he is put in the way of receiving perpetually the greatest advantages. His motive, therefore, to obtain the favourable and to avoid the unfavourable regards of the members of the society in which he lives, is of the highest order. But he can obtain their favourable, and avoid their unfavourable sentiments, only by abstaining, with scrupulous anxiety, from doing any injury to them, and observing all such modes of conduct as are calculated to be useful and agreeable to them.

The value which men set upon these favourable regards of the persons among whom they live, is strikingly manifested by some of the most ordinary forms of their dis-

Law of Nations.

course and behaviour. What is more esteemed than character? What injury reckoned more deep and unpardonable, than that of the man who exerts himself to take away unworthily any part of the reputation of his neighbours? But what is character, if not the title to the favourable sentiments of other men? And what is the loss of character, but the opinion of other men that we do not deserve those favourable sentiments with which they have been accustomed to regard us?

Honour and shame, those emotions, the intensity of which is proved by so many phenomena of human life, are but the feelings which attend upon those different situations. When a man finds himself in possession of the love, the esteem, and admiration of those by whom he is surrounded, he is filled with that delight which the belief of the secure possession of a great source of benefit cannot fail to inspire: he is fearless, elated, and confident; the principal characteristics of that state of mind which we denominate pride. When he is conscious, on the other hand, of having forfeited in any degree the favourable sentiments of those among whom he lives, he suffers that depression which the loss of a highly valued possession is calculated to create; he ceases, in some degree, to look forward to his fellow-men for good, and feels more or less the apprehension of evil at their hands; he fears to prove how far their disapprobation of him reaches, or to excite them to define it too accurately for themselves; he hangs down his head, and dares not so much as look them in the face.

When men are favourably situated for having those impressions deeply struck, or, more correctly speaking, when those combinations of ideas have consistently and habitually been presented to their minds, the association becomes at last so indissoluble and strong, as to operate, even where the connection among the things themselves may not exist.

When persons who have been educated in a virtuous society have, from their infancy, associated the idea of certain actions with the favourable sentiments, and all the advantages which flow from the favourable sentiments, of mankind; and, on the other hand, have associated the idea of certain other actions with the unfavourable sentiments, and all the disadvantages which flow from the unfavourable sentiments, of mankind; so painful a feeling comes in time to be raised in them at the very thought of any such action, that they recoil from the perpetration of it, even in cases in which they may be perfectly secure against any unfavourable sentiments which it might be calculated to inspire.

It will, we apprehend, upon the most accurate investigation, be found, that this is the only power to which we can look for any considerable sanction to the laws of nations; for almost the only species of punishment to which the violation of them can ever become amenable: it is the only security, therefore, which mankind can ever enjoy for the benefit which laws, well contrived for this purpose, might be calculated to yield.

It is, in the next place, incumbent upon us to inquire, what dependence can be placed upon this security, in the set of cases now under consideration; and in what circumstances it is calculated to act with the greatest, in what with the least efficacy, towards this important end.

A power which is wholly derived from the good which may follow the favourable, the evil which may follow the unfavourable, sentiments of mankind, will act most efficaciously upon him who is the most, least efficaciously upon him who is the least, exposed to receive good and evil from the immediate inclination of his fellow-men.

It seems to be evident, that he who is most weak, as compared with the rest of the community, is the most exposed to receive good or evil in consequence of their fa-

vourable or unfavourable sentiments; and that he, on the other hand, who is the most powerful, as compared with them, is the least exposed to receive good or evil in consequence of those sentiments.

When men are nearly upon equality, no one has any chance of inducing other people to abstain from hurting him, but by his abstaining from doing hurt in any way to them. He has no means of inducing them to do him any acts of service, but by their expectation of receiving similar acts of service from him. He is, therefore, intensely interested in its being generally believed of him, that he is a man who is careful to abstain from injuring, and ever ready to exert himself to do services to others.

The case is exceedingly different where one man is lifted high above others. In that case, he has powerful means of protection against their hurtful acts, powerful means of obtaining their services, altogether independent of his conduct, altogether independent of his disposition either to abstain from injuring them, or to render them service.

So far, therefore, as good conduct arises from a man's dependence upon the sentiments of others; and from this is derived the moral power, to which alone the term moral sanction or obligation can properly belong; the security for good conduct is apt to be lessened, in exact proportion as any one is raised above the level of those composing the mass of the community. If any man possesses absolute power over the rest of the community, he is set free from all dependence upon their sentiments. In this, or nearly in this situation, is every despot having a well-established authority. So far as a man is educated as a despot, he can therefore have but few of those associations on which a conduct beneficent to others depends. He is not accustomed to look, for the services which he needs, or the evils which he apprehends, from others, to the opinion which they may entertain of the goodness or badness of his conduct; he cannot, therefore, have that salutary train of transitions from the idea of an evil act to that of the condemnatory sentiments of mankind, and from the condemnatory sentiments of mankind to the forfeiture of all those delights and advantages which spring to him from the operation of their favourable regards; associations which in men favourably situated become at last habitual, and govern the conduct, as it were mechanically, without any distinct recurrence to the consequences, upon the thought of which, nevertheless, this salutary and ennobling sentiment ultimately depends, and from which it has been originally derived.

If such is the situation of the despot with regard to these important associations, it is in a proportional degree the situation of all those who partake of that species of elevation. In an aristocratical country, for example, a country in which there is great inequality of wealth, those who possess the large fortunes are raised to a great degree above any chance of receiving evil, or of standing deprived of any good, because the great mass, the lower orders, of their countrymen, think unfavourably of them. They are, no doubt, to a considerable degree dependent upon what the people of their own class may think of them; and it is accordingly found, that those qualities and acts which are useful to that class are formed into a particular, an aristocratical code of morality, which is very effectually sanctioned by the favourable and unfavourable sentiments of the aristocratical body, at the same time that it is exceedingly different from that more enlarged and all-comprehensive code, on which the happiness of the greatest number depends, and to which alone the epithet moral in propriety belongs.

Such being the state of the facts connected with this important case, it remains to see what are the inferences bearing upon it which we are entitled to draw from them.

Law of Nations.

Law of Nations.

We have already ascertained, that the only power which can operate to sanction the laws of nations, in other words, to reward or punish any nation, according as it obeys or as it disobeys them, is the approbation and disapprobation of mankind. It follows, that the restraining force is, in this case, determined by the associations which they who govern it may have formed with the approbation and disapprobation of mankind. If they have formed strong associations of a pleasurable kind with the approbation, strong associations of the painful kind with the disapprobation, of mankind, the restraining force will be great; if they have not formed such associations, it will be feeble and insignificant. It has, however, appeared, immediately above, that the rulers of a country, of which the government is either monarchical or aristocratical, can have these associations in but a very low degree; as those alone, who are placed on a level with the great body of other men, are placed in circumstances calculated to produce them. It is only then in countries, the rulers of which are drawn from the mass of the people, in other words, in democratical countries, that the sanction of the laws of nations can be expected to operate with any considerable effect.

II.—*What is required to give to the Law of Nations its greatest perfection.—Necessity for a Code of International Law.—Rights of Nations.*

Having thus ascertained what is the power which restrains from violating the laws of nations, and what the description of rulers upon whom its restraining force is the greatest, we are next to inquire by what expedients the force of it may be raised to the greatest pitch, and the greatest amount of benefit may be derived from it.

It is sufficiently recognised, that whatever is intended to produce any effect as a punishment, produces it in a greater degree, in proportion as it operates with greater precision and certainty. The inquiry, then, regards the means of giving precision and certainty to those sentiments of the world, on which the binding power of the laws of nations so greatly depends.

Two things are necessary to give precision and certainty to the operation of laws within a community. The one is a strict determination of what the law is; the second, a tribunal so constituted as to yield prompt and accurate execution to the law. It is evident that these two are indispensable requisites. Without them no penalties can operate with either precision or certainty. And the case is evidently the same, whether we speak of the laws which regulate the actions of individual and individual within the state, or those which regulate the actions of one state towards another.

It is obvious to remark, in the first place, that, with regard to the laws of nations, not one of those two indispensable requisites has ever yet had any existence. It has neither been determined what the laws in question are, nor has any common tribunal for cognizance of the violations of them ever been constituted. With respect to the last, not so much as the idea of it seems to have been entertained. And with respect to the first, though much has been written, it has been almost wholly in the way of vague and general discourse. Hardly a single accurate definition has yet been applied to any part of the subject.

Here, then, we come to what is obviously the grand inquiry; namely, *first*, what can be done towards defining the laws of nations? and, *secondly*, what can be done towards providing a tribunal for yielding prompt and accurate decisions in conformity with them? in other words, for applying with the greatest possible efficacy the opinion of the world for restraining the violation of them?

In the preceding article, to which it is necessary for us

here to revert, we have sufficiently made it appear, that the foundation of all law is the constitution of rights. Of two parties, unless it is previously determined what each shall enjoy, it can never be determined whether one has improperly disturbed the enjoyment of the other. To determine, however, what a party is to enjoy, is to determine his rights.

Now then, with regard to nations, the question is, what ought to be constituted rights? or, in other words, what would it be desirable for the good of mankind upon the whole, that the several nations should respect as the rights of each other?

This, it is pretty obvious, is one of the most extensive of all inquiries, far exceeding the limits of an article in the present work. We can attempt little more than to show the way in which the inquiry may be carried on.

In the preceding article, we have endeavoured to clear up the meaning which in legislation can, without leading to confusion, be alone attached to the term *rights*; and we have there likewise seen, that there are but two classes of objects in which individuals can have rights, namely, things and persons.

The case, we believe, will be found the same with respect to nations. They also can have rights in nothing but persons and things. Of course it follows that they can receive injury in nothing but in persons or things.

The inquiry, however, with respect to the rights of nations, is not so simple as that with respect to the rights of individuals; because, between individuals subject to the same system of laws, the legislature recognises no state of hostility; but between nations there is the state of war and the state of peace, and the rights which are understood to belong to nations are different in these two different states. In the state of war, nations recognise in one another very few rights respecting either persons or things; they kill the one, and take and destroy the other, with little other limit than the want of ability. In the state of peace they respect as rights belonging to one another, nearly the same things which are constituted rights of individuals, by the ordinary systems of national law.

III.—*What should be recognised as Rights in time of Peace.—The Property of Individuals.—The Persons of Individuals.—The Property or Dominion of the State.—Dominion in Land.—Dominion in Water.*

We shall begin with the consideration of those things which it would be desirable that nations should respect as the rights of one another in the time of peace.

And, *first*, of rights with respect to things. As the subject of the rights of nations, things may be divided into two sorts; things belonging to some individual member of the nation, and things belonging to the nation in its collective or corporate capacity.

Those rights in things which the nation guarantees to its individual members within the nation, it would be desirable, with hardly any exception, that nations should respect in regard to one another; that those things, for example, which the government of the country to which a man belongs, would regard, and would compel all its subjects to regard, as his property, the governments of all other countries should respect, and compel all their subjects to respect as his property.

There are two states of circumstances in which questions may arise between nations, respecting the property of their respective subjects. The first, where the property in question, when the cause of dispute arises, is within the country of the individual to whom it belongs. The second, where the property has by its owner been previously removed into the foreign country, with which, or some of the inhabitants of which, the dispute has arisen.

Law of Nations.

Law of Nations.

1. The first set of circumstances exists between two conterminous countries, the bordering inhabitants of which being neighbours to one another, may, as any other neighbours, infringe the properties of one another. The proper mode of settling these disputes seems to be sufficiently obvious. The rights of the party complaining should be adjudged according to the laws of the country to which he belongs. But the party sued or prosecuted should be amenable only to the tribunals of the country to which he belongs; that is to say, the question should be tried before the tribunals of the country of the defendant; but the definition of the right in question should be taken from the law of the country to which the plaintiff belongs. It might in some cases be convenient for countries in this situation to agree in constituting a common judicature, appropriated to these disputes, to consist, for example, of two judges, one of each country, with power to choose a third when they could not agree.

The injury complained of may be capable of redress by a remedy of the nature of a civil suit merely; or it may be of that more atrocious sort, theft or robbery, for which the remedy of punishment is required.

It would appear that punishment ought to be apportioned according to the laws of the country to which the party who has incurred it belongs. Whatever would be the punishment decreed for the offence, if committed against a man of his own country, such a punishment he ought to sustain for the offence against the man of the other country. The question of punishment is here understood as extraneous to that of compensation. This ought always to be made to the party injured, where it is capable of being made, and in a case of property it is always capable; if not by the author of the injury, from want of property, or other cause, at least by the government of the country to which he belongs.

2. Where a man has removed his property from his own into another country, there seems to be no peculiar reason why it should be regulated by any other laws than those of the country into which he has removed it; why the rights which it confers should be otherwise determined, or the violation of them otherwise punished.

We have now considered, though in a very general manner (and our limits preclude us from attempting any thing more), the mode in which nations should agree about the rights of one another (in other words, the laws they should establish), in as far as the property of individuals belonging to them is concerned. After the *property* of individuals, their *persons* are to be considered as requiring the protection of laws.

There is more difficulty in determining what is desirable, as international law, with regard to this part of the subject, than that which regards the property of individuals. It is desirable that the persons of the inhabitants of every country should receive protection according to the laws of their own country; but it is also desirable that each man should sustain punishment according to the laws of his country; and these two objects are to a certain extent inconsistent with one another.

The inconvenience, however, seems to be greater, in permitting the inhabitants of one country to be punished according to the laws of another, than in leaving the inhabitants of one country to the same measure of protection against injury to their persons from the inhabitants of other countries, as is afforded to the inhabitants of those countries by their own laws. Many cases, indeed, may be conceived, in which this is a measure of protection which all reasonable men would allow to be inadequate. In such cases, however, the only remedy seems to be the formation of a compact, by which a mode of proceeding, agreeable to the sentiments of both parties, may be positively prescribed. This latter expedient is of course extraneous

Law of Nations.

to that equitable construction which ought to be uniformly applied by the tribunals of one country to the injuries perpetrated, by those whom they may have to judge, upon the inhabitants of another country. If an inhabitant of Persia, for example, should force cow-broth down the throat of an inhabitant and native of Hindustan, the tribunals of Persia should not punish this outrage as they would punish one Persian for making another swallow the same liquid. To the Persian it would be a trifling injury, and more than a trifling punishment would not be required. To the Hindu it would be one of the greatest of all conceivable injuries. It ought to be, therefore, put upon the same footing with an injury of an equal degree done to a Persian; the nature of the injury, not the external act, should be the object of consideration; and whatever the punishment which would be awarded against a Persian for one of the greatest injuries of which he could be guilty to a Persian, the same ought to be inflicted upon him for this, one of the greatest which he could occasion to a Hindu.

Besides the cases in which a government, as representative of the country, may be injured through the individuals who live under its protection, there are cases in which it may be injured more directly. Certain things belong as property to the government, without belonging to any individual; and there are persons, members of the government, or agents of the government, who may receive injuries in that capacity, distinct from those which affect them as private individuals. These are the cases to which it now remains that we direct our attention.

Those things which belong to government as goods and chattels; its moveables, for example; or the lands which it holds, as any individual holds them, in the way of an estate; there seems to be no reason for considering as subject to any other rules than those applicable to the goods and chattels which belong to individuals.

Of other things, those to which any government can claim a right, as representative of a nation, must be either, first, portions of land, or, secondly, portions of water.

1. The questions which relate to the rights which any nation may claim in any portion of land, are questions regarding boundaries; and these involve the whole of the questions respecting the acquisition of dominion.

To have any standard for determining questions with regard to dominion, the different modes of acquiring dominion must be recognised; those which are proper to be allowed and respected by other nations must be distinguished from those which are improper, must be accurately defined, and the definitions made known.

For this purpose it is easy to perceive that the same process is necessary as that for the definition of rights, described in the section JURISPRUDENCE of the preceding article to which we must again refer.

It is necessary, according to that example, that the events which are to be considered as giving commencement to a right of dominion, and those which are to be considered as putting an end to it, should be fully enumerated, and accurately defined.

This is the first part of the process. The other part is, to distinguish the different degrees of dominion. There is a dominion which is perfect, which includes every power over the subject in question, and leaves nothing farther to be acquired, a *dominium plenum*; there is also a dominion, which is but the commencement, as it were, of dominion, and includes the smallest possible fragment of a full dominion. These are the two extremes; and between them are various distinguishable degrees. All these should be fully enumerated, and accurately defined.

When any of those events occurs which are to be considered as giving commencement to rights, it often happens that they are accompanied by circumstances which limit the right they would otherwise convey, and render

Law of Nations.

the dominion less than full. These circumstances ought also to be completely enumerated, and the power of each to be accurately defined.

If this were done, an international code would be composed, in which the rights of dominion would be accurately defined; and to determine any question about boundaries, or about the degree of dominion, nothing farther would then be necessary than an adequate inquiry respecting the state of the facts.

The questions would exactly resemble those which we have already described in the preceding article in analyzing what is called pleading in judicature. In a question about boundaries there is, let us suppose, a district over which one country affirms that it has a right of dominion, a dominion more or less complete, and another country denies that it has that right. The first question is, whether any of those events has occurred which would give the affirming country a right of dominion? The second question is, whether, if such an event had occurred, it was accompanied with any of those circumstances which limit dominion, and render it less than full; and if so, under what degree of limiting power they are classed? The third question is, whether, if an event thus giving commencement to a right of dominion had occurred, any other event putting an end to that right had subsequently occurred?

We need not here enlarge upon these several topics, because they will be sufficiently understood by those readers who bear in mind the expositions already given in the article referred to; and to those who do not, we suggest the propriety of recurring to that article, as a preparation for the perusal of this.

It is evidently disproportionate to the limits which we must here prescribe to ourselves, to enumerate the events which it would be agreeable to the interests of mankind in general that nations should regard as giving, and alone giving, commencement and termination to rights of dominion, because, in order to afford an enumeration which would be in any degree instructive, the reasons must be given why one set of events, and not another, should have the privilege in question conferred upon them.

It may be proper, however, in the mean time, to observe, that the events in question will not be found to be numerous, nor very difficult to discover. In fact they are, and among civilized nations almost always have been, pretty nearly agreed upon; and they are the questions of modification, and questions of fact, upon which chiefly differences have arisen. For example, there is no dispute that occupancy, where there is no prior right, is an event which should be considered as giving commencement to a right of dominion. Neither is there any doubt that the consent of those who have a right may transfer that right to others; or, in other words, that such consent is an event which gives commencement to a right in those others. Conquest, also, made in a lawful war, is recognised as an event of the same description; and it will be found upon inquiry that these do in fact constitute the whole. For, on every occasion on which dominion is acquired, the territory so acquired must beforehand either have belonged to somebody, or have belonged to nobody. If it belonged to nobody, occupancy is the only event which can be supposed to give commencement to the right. If it belonged to somebody, it must be taken from him, either willingly or by force. If it is taken from him willingly, we have his consent. If it is taken by force, it is by conquest in war that the new right is created.

It is evidently, however, farther necessary, that the different species of consent should be distinguished, and those to which it would be proper to attach this investitive power separated accurately from those from which it should be withheld. It is here, accordingly, that the

Law of Nations.

doctrine of contracts would need to be introduced; that the different species of them applicable to this subject, in which all treaties would be included, should be enumerated; that the effects proper to be given to each of them should be defined; and the mode of interpreting them, or fixing the sense which they ought to bear, accurately laid down.

It would also be expedient, after the principal contracts applicable to international concerns are ascertained, to exhibit in the international code, *formule*, with blanks to be filled up, which should be employed by nations on all occasions of such contracts; and, being framed with the greatest possible accuracy, would go as far as it would be possible by words to go, in excluding ambiguity and the grounds of dispute.

With respect to conquest, the last event calculated to give commencement to rights of dominion mentioned in the above general enumeration, it is allowed, that as there are some conquests which ought not to be considered as conferring rights of dominion, there are others which ought to be considered as doing so. It is evidently necessary, therefore, that the line of separation should be drawn.

Whether a conquest, however, should or should not be considered as conferring a right of dominion, depends very much upon the nature of the war through which it is made. If the war be what is regarded as just, and the mode of warfare conformable to the recognised rules, the conquest is apt to be regarded as conferring a legitimate title; if the war, and mode of war, be of a contrary description, the validity of the title conferred by the conquest may be liable to dispute.

It is evident, therefore, that in order to define the species of conquest on which the investitive power in question should be conferred, the circumstances which render a war justifiable, and the mode in which it is justifiable to carry it on, must first be ascertained. This forms the second part of our inquiry; and the question regarding the investitive power of conquest must be deferred till that inquiry is performed.

2. Having thus far considered the mode in which should be determined the rights which nations acquire over portions of territory or land, it remains that we consider the mode in which their rights should be determined with regard to waters.

Waters, as concerns the present purpose, are either rivers or the sea.

As the sea involves the questions of greatest extent and importance, we shall attend to that part of the subject first.

Even in the language of ordinary discourse, the sea is denominated the common domain of nations.

The first principle with regard to the sea is this, that all nations have an equal right to the use of it. The utility of recognising this principle is so apparent, that it has never been the subject of any dispute. And all the rights assigned to nations severally in the enjoyment of this common domain ought to rise out of this principle, and to be limited by it. Whatever use any nation makes of it, should be such as not to prevent a similar and equal use from being made by other nations. And every use which cannot be shown to have that effect, should be recognised as a right by the law of nations.

The principal use which nations make of the sea is that of a passage for their ships. Agreeably to the principle which we have recognised, the ships of one nation should pass in such a manner as not to obstruct the passage of those of another. The rules according to which the possible cases of interference should be regulated are very simple, and are, in fact, laid down and acted upon with considerable accuracy. They resemble in all respects those according to which the vessels of the same country are made to avoid and to regulate their interferences in

Law of Nations.

the rivers of the country, or upon its coasts. There would be no difficulty, therefore, in making accurate definitions of the requisite rights, for insertion in the international code.

The rights being established, the violations of them should be punished, on the same principles as those which we have laid down in regard to the preceding cases. Either property has been injured, or persons. In either case, compensation is an indisputable part of the remedial process, wherever it is practicable. In loss of property it is fully practicable. It is also practicable in many of the injuries done to the person. As in the case of offences committed on land, the rights of the individual who has suffered should be estimated according to the laws of the country to which he belongs; but the punishment of the offender should be measured according to the laws of the country to which he belongs. In the case of piracy, which is robbery or murder committed by persons whom no country recognises, and upon whom, therefore, justice can be demanded from no foreign government, it has hitherto been the practice that the nation suffering has taken the punishment into its own hands. Accordingly, the punishment of piracy has always been extremely severe. It would be no doubt better if a mode were adopted by which it would not be necessary for a nation to be judge in its own cause. A rule does not seem impossible to be framed, according to which the punishment of piracy might be provided for, by referring those accused of it either to some general tribunal constituted for that purpose, or to the tribunals of some nation other than that against which the offence has been perpetrated. A general law on this subject, to be observed by all nations, would be highly desirable.

Rules, therefore, seem not difficult to be laid down for regulating the proceedings of nations on the high seas. A distinction, however, is drawn between what is called the *high*, and what is called the *narrow seas*. By the narrow seas is commonly meant some portion of sea to a greater or less extent immediately surrounding a particular country, and in which that country claims peculiar privileges. The question is, whether any such privileges should be allowed, and, if allowed, to what extent?

The regulating principle in this, as in other cases, is the general advantage, the principle of utility. There are cases in which certain privileges in the waters surrounding a particular country are of so much importance to that country, and the exercise of those advantages occasions so very little inconvenience to other nations, that what is lost by all of them taken together bears no comparison with what is gained by that particular nation. In these cases the exercise of such privileges should be allowed; they should, however, be defined, in as many instances as possible, and promulgated by insertion in an international code.

Of the privileges in question, are all those which are essential, or to a considerable degree subservient, to the national security. In some cases the exclusive right of fishing might perhaps come under the same rule. But this is in general provided for by the necessity of drawing the nets, or curing the fish, upon the land, a privilege which, of course, it is in the power of any nation to give or to withhold.

In obedience to this equitable principle, it appears that such foppish privileges as have sometimes been insisted upon, affording no advantage to one nation which is not wholly at the cost of others (lowering the flag, for example, and such like impositions), should not be recognised by the code of nations.

It appears, also, that those tolls which have been sometimes and are levied at the narrow inlets of some seas, deserve to fall under the same condemnation. The passage through these inlets is a common good to all the nations

of the earth which may have a motive to use them, a good of the highest importance to the nations which are situated within, and to which it is the only means of maritime communication; and, while it imparts no evil to the conterminous nation, the toll which that nation levies is an advantage obtained wholly at the cost of others, and imposing upon them a burden, in the way of obstruction and trouble, which is compensated for by advantage to nobody.

The waters, we have said, in respect to which rights should be assigned to nations, are rivers and the sea. Having stated what appears necessary on the present occasion with respect to the sea, it remains that we offer the few observations required on the subject of rivers.

Rivers are either the boundary between two countries, or they are wholly within a particular country.

Those which are wholly within a particular country, it seems most agreeable to the principle of utility to regard as wholly belonging to that country. In the case of navigable rivers which pass through several countries, it would indeed be desirable for those countries which are situated higher up than at the mouth of each, as well as for all those who might thus have intercourse with them, that the navigation of such rivers should be free; but it would be difficult so to regulate this right, as not to affect the security of the country through which a free navigation should thus be allowed; and a slight diminution in its security would be so great a loss to that country as would require, to compensate for it, a very great advantage to those by whom the navigation was enjoyed. Unless where this advantage were very great, it would not, therefore, be agreeable to the principle which should dictate the laws of nations, that the freedom of the navigation should be regulated on any other principles than those of mutual agreement.

In regard to those rivers which flow between two countries, the principle of regulation is sufficiently plain. The benefits derivable from the river should be shared equally between them. Its principal benefits arise from the fishing and from the navigation. The right of fishing in most cases may be fitly distributed, by each party fishing from its own bank to the middle of the stream. The right of navigating of each must be so exercised as not to obstruct the right of the other. In this case the same sort of rules are required to prevent the ships of the two nations from obstructing one another in a common river, as are found available to prevent the ships of different individuals from obstructing one another in a river belonging to one country. There is no difficulty, therefore, here, which it is worth stopping to show how to remove.

IV.—*What should be recognised as Rights in time of War. —What should be regarded as necessary to render the Commencement of a War just.—What should be regarded as just and unjust in the Modes of carrying on a War.*

We have now adduced what our limits admit to be said upon the first great branch of the inquiry relative to the law of nations, namely, the rights which they should recognise in one another in the state of peace. We proceed to the second branch, relating wholly to the state of war.

The questions which present themselves for solution relating to the state of war, are either those which respect its commencement, or those which respect the mode of carrying it on.

With respect to the commencement of a war, the principal question is, What are the conditions which should be regarded as necessary to render it just?

As men, in a situation where laws, and the protection derived from them, do not exist, are left to their own protection, and have no means of deterring other men from

Law of Nations.

Law of Nations.

injuring them, but making them dread injury in return; so nations, which, with respect to one another, have, as we have seen before, but little protection from the legal sanction, are left to supply its place by this dread of injury in return, which, in the case both of individuals and of nations, may be called the *retributive sanction*, and of which, in the case of nations, war is the principal organ.

From this view of the essence and end of war, we lay down immediately one pretty extensive proposition with regard to the conditions necessary to render it just.

As the legal sanction, or punishment for the offences of individuals, ought to operate only where some right has been violated, and the violation has been such as to require it, so the retributive sanction of nations, which is war, ought to operate only where some right of the nation, or something which ought to be traced as a right, has been violated, and where the violation has been such as to require that desperate remedy.

But as not all violations which may possibly be committed of the rights of a nation will justify it in inflicting war, the next object is to draw the line of separation, and distinguish between those violations of the rights of nations which justify, and those which do not justify, the extremity of war.

As the evils which war produces are exceedingly great, it is, first of all, evident, that no violation of rights which is not very great, will, upon the principle which we have so often recognised, suffice to justify it. Of two evils, the least is the choice of all sound legislation.

Of the violation of the rights of individuals in the same country, the cases meet for punishment are capable of being pointed out with a degree of accuracy not wanting much of perfection. Of the violation of the rights of nations committed by one nation against another, the cases which would justify the remedial operation of war are much more difficult to define. The difficulty, indeed, is not universal; for there are cases which may be very satisfactorily defined; and as far as definition can go, it is of the utmost importance that it should be carried. Uncertainty, then, pervades only one part of the field; which the more we are able to lessen, the greater is the advantage in favour of humanity. If a proper code of international law were formed, there would be certain defined violations of the rights of nations which would be pointed out, not only as deserving the indignation and hatred of all the world, but as justifying the injured nation before all the world, in inflicting upon its injurer the calamities of war. There would also be certain other injuries pointed out, of a more doubtful character, which might, or might not, according to circumstances not easy to define, be such as to justify recourse to war. The injuries of this secondary character, also, which might, or might not, according to circumstances, justify a war, are capable of being pointed out with a certain degree of accuracy. To a certain degree, likewise, the circumstances which would convert them into justifying causes, are capable of being foreseen. So far definition is capable of extending, and so far, of course, it ought to be carried.

In illustration of this latter class of injuries, we may select the most remarkable, perhaps, and important of all the instances; preparations for a threatened attack. A sense of security is one of the most valuable treasures of a nation; and to be deprived of that sense of security, is one of the greatest injuries. But what state of preparation shall or shall not be considered as justifying the threatened nation in striking the first blow, in order not to give its enemy the advantage of completing his preparations, and making his attack just at the moment when it would be most destructive, it is perhaps impossible to determine for all cases beforehand; though, no doubt, a certain progress may be made towards that determination, and the bounds of uncertainty may be greatly reduced.

Law of Nations.

We are aware how general, and therefore how unsatisfactory, these observations are, on the important subject of defining those violations of the rights of nations, which ought to be regarded as justificatory causes of war; but at the same time it is to be observed, that not much more could have been done without framing the code, by actually enumerating and defining the violations for which that remedy should be reserved.

Another consideration is now to be weighed. It is evident, that whatever injuries are done by one nation to another, compensation may almost always be made for them. It is equally evident, that whatever injury may have been sustained, if compensation is made for it, the justificatory cause of war is removed.

The doctrine of compensation, therefore, is an important part of international jurisprudence. Before recourse is had to war for any violation of rights, compensation ought first to be demanded; and no war, except in cases fit for exception, should be regarded as just, which this demand had not preceded; a demand which should be made through a constituted organ, and in a predetermined mode, as we shall more fully describe in a subsequent page, when we come to treat of an international tribunal.

As there can be no reason why the demand of compensation should not always precede the use of arms, except in cases of such a necessity as will not allow time for demanding compensation, a necessity for the immediate use of arms, in order to prevent an evil immediately impending, those cases of urgent necessity should, as far as possible, be sought out and defined.

Other circumstances may be enumerated, as belonging to this first stage of the remedy against a nation which places itself in an attitude affecting the sense of security of any of its neighbours. If a nation is making preparations, or executing any other measures calculated to excite alarm, it may be called upon to desist from them; or it may be called upon to give security that it will not make a hostile use of them. Of these securities, hostages are one of the most familiar instances. Various other instances will easily present themselves to the consideration of our readers. Upon this part of the subject, therefore, it is unnecessary for us to enlarge.

It thus appears, that we may lay down, with a considerable degree of precision, the conditions upon which the commencement of a war ought to be regarded as just. It remains, under this head of inquiry, that we show how it may, as far as possible, be determined, what ought to be regarded as just and unjust in the modes of carrying it on.

This is an inquiry of more complexity, a good deal, than the first. In looking out for a guiding principle, it is evidently necessary to keep in view the end to which every just war is of necessity restricted. That is, compensation for an injury received, and security that a fresh injury shall not be committed. Combining this with the grand principle of humanity and utility, in other words, of morality; namely, that all evil, wilfully occasioned, and not calculated to produce a more than equivalent good, is wicked, and to be opposed, we obtain one comprehensive and highly important rule; which is this: That in the modes of carrying on war, everything should be condemned by the law of nations, which, without being more conducive, or more in any considerable degree to the attainment of the just end of the war, is much more mischievous to the nation against whom it is done.

As the end is to be gained, in most cases, only by inflicting a loss of men and property upon the opposing nation, it would be desirable that the distinction should be drawn between the modes of inflicting this loss, which are the most, and those which are the least, calculated to inflict pain and suffering, without being more conducive to the end.

Law of Nations.

One distinction is sufficiently remarkable; namely, the distinction between the men who are in arms, or actually opposed to the designs of the belligerent, and the men who are not so; also between the property which belongs to the government of the opposing nation, and that which belongs to private individuals composing the nation.

With respect to the first class of objects, the men in arms, and the property of the government, there is not much difficulty. To produce the loss of them, as rapidly as possible, till the end or purpose of the war is obtained, appears to be a privilege which cannot be separated from the right of warring at all.

With respect to the loss of men, indeed, there is an important restriction. It means the loss of them for the purposes of the war, and no more. If it be practicable to put them in a situation in which they can no longer be of any service to the war, all farther injury to them should be held unjustifiable. Under this rule falls the obligation so generally recognised of making our enemies, as often as possible, prisoners, instead of killing them, and of treating them with humanity while retained in that condition.

That part of the subject, therefore, which relates to men in arms, and to such property as belongs immediately to the government, it is not impossible to include in rules of tolerable precision. The difficulty is with respect to those individuals who, composing the body of the nation, form no part of the men in arms, and with respect to the property of such individuals.

Though it would not be correct to say, that these do not contribute, or rather that they may not be made to contribute, to the means with which the government carries on the war; yet it would be absurd not to recognise a very broad distinction between them and the men and things which are immediately applied, or applicable to the war. A difference, therefore, equally broad, ought, in reason, to be made in the mode of treating them. The mode of treating the one ought to be very different from that of treating the other. As the rule of destruction must be the rule with regard to the first, only limited by certain restrictions; so the rule of forbearance and preservation ought to be the rule with regard to the latter, only to be infringed upon special and justifying circumstances.

Thus far we seem to have travelled with the advantage of light to our path. We may go a little farther with equal certainty, and say, that, as far as regards the persons of those who are not engaged in the immediate business of hostility, very few occasions can occur, in which it would be allowable, upon any just principle of international law, to do them any injury. Leaving them out of the question, we narrow it to the case of the property belonging to individuals; and shall now proceed to see how far the protection of it can be embraced within general rules.

We must suppose the case which is the strongest, that of an invading army. The advantage which is capable of being derived to such an enemy, by seizing and destroying the property of individuals, bears, unless in certain very extraordinary instances, no sort of proportion to the evil inflicted upon the individuals. This, we presume, cannot admit of a dispute. Upon the principle, therefore, so often recognised, as dictating the rules which ought in this affair to be solely obeyed, no such destruction, unless in such instances, ought to be sanctioned by the law of nations. Such property, it is well known, can rarely be counted upon as any considerable resource; because it is to a very great extent in the power of the people invaded to drive their property away, or to destroy it. The property of individuals in an invaded country would in general be a much more certain resource to an invading army, if that army were to purchase from them the articles it desired. And, perhaps, this would be the most advantageous compromise of which the circumstances admit; namely, that

Law of Nations.

the invading army should abstain from the violation of private property, but that it should in return have the benefit of an unrestricted market; that nothing should be done on the part of the government of the invaded country to prevent its subjects from buying and selling with the invaders, as they would with any other parties.

It may no doubt be true, that the plunder and devastation of a province, or other portion of a country, must have an effect in diminishing the resources of the government for carrying on the war. In this point of view, it must be allowed that the destruction of private property is of some importance to the invading nation with regard to the result of the war. But the question, in settling the difficulties of international jurisprudence, is not whether an advantage is gained, but whether the advantage, such as it is, be not gained at too great a cost.

If it be certain that the losing party, in consequence of the destruction in question, loses more than the gaining party gains, it is certain that the two parties, taken together, are losers by the proceeding; and of course that nations, in the aggregate, are losers upon the whole. Nay, it is certain that each nation, taken by itself, is a loser, upon the balance of the cases in which it is liable to lose, and those in which it is liable to gain. If it loses more in the cases in which it bears, than it gains in the cases in which it inflicts invasion, and if it is as liable to bear as to inflict, which is the usual condition of nations, it follows clearly that it is its interest to concur in a rule which shall protect the property of individuals in cases of invasion.

Even in that more civilized mode which has been adopted by invading armies, of availing themselves of the property of individuals, by exacting contributions through the instrumentality of the local authorities; contributions which these authorities are left to partition among the people, as they may deem equitable; though it is admitted that this is a much less hurtful proceeding than military rapine, still we think it will easily appear, that the evil inflicted upon the contributors is greater than the benefits derived to the receivers.

Unless the amount thus received by an invading army is very considerable, the benefit which is derived, the aid which is gained towards accomplishing the end of the war, must be considered as trifling. But if a contribution, the amount of which can be of any considerable avail towards attaining the object of the war, is levied suddenly upon a particular district, a comparatively small portion of the invaded country, it must operate upon the contributors with a dreadful weight of oppression. Upon an equal estimate of the circumstances, it can, therefore, hardly fail to appear that, whether the contribution exacted is heavy or light (it must always be heavy to those who sustain it), the loss to those who suffer must greatly outweigh the advantage to those who receive. If it be so, this mode of exaction should, it is evident, be forbidden by the law of nations.

If these are the principles upon which an international code, regarding this branch of the subject, ought to be constructed, they will enable us to determine the question with regard to the property of individuals in another set of circumstances, to which the rules of civilized society have hardly yet begun to be applied. Whatever rules apply to the property of individuals found upon the land, the same rules ought, by parity of reason, it should seem, to apply to it when found upon the sea.

The conduct of nations, however, has hitherto not been conformable to the parity which appears to belong to the two sets of cases. Some tenderness, more or less, according to the progress of civilization, appears to have been shown, by all but savages, to the property of individuals upon the land. To this hour the property of individuals upon the sea is made prize of without mercy, by the most civilized nations in the world.

Law of Nations.

The notions of piracy, in fact, have, on this subject, unhappily prevailed, and governed the minds of men. Pirates make prey of everything. Sailors, originally, were all pirates. The seafaring state was a belligerent state, of almost every vessel against every other vessel. Even when nations had gradually advanced into a more civilized state, and when their vessels abstained from injury to one another in a period of peace, they appear, when the ties of peace were dissolved, and they were placed with respect to one another in a state of war upon the seas, to have felt the force of none but their old associations, and to have looked upon the state of war as a state of piracy. Two nations at war with one another continue to act towards the property of individuals belonging to one another at sea, exactly as two nations of pirates would do.

Assuredly this is a state of things to which the present intelligence and morality of the world ought speedily to put an end. The very same reasoning which we have applied to the case of the property of individuals upon the land, is not less conclusive when applied to the property of individuals upon the sea. The loss to the party losing is more than an equivalent for the gain to the party that gains.

There is another consideration of great importance. All nations gain by the free operations of commerce. If, then, we were to suppose that the losses and gains of the two belligerent parties balanced one another, which yet they never do, there is an advantage derived from their commerce to every nation on the earth to which, in any degree, either directly or indirectly, that commerce extends; which advantage is either lost or diminished, by their preying upon the property of the individuals belonging to one another. This, therefore, is an unquestionable balance of loss to the general community of nations, which the law of that community ought to endeavour to prevent.

If, then, we should suppose that it were enacted as the law of nations, that the property of individuals passing on the seas should be equally respected in peace and in war, we may proceed to consider whether any disadvantage, nearly countervailing the general good, would thence accrue to the belligerents.

It may be alleged, that a nation at war with another is retarded in reducing its antagonist, by the riches which the commerce of that antagonist, if undisturbed, will place at its disposal. But it is evident that an advantage to one of two antagonists, when compensated to the other, by a power to overcome that advantage, exactly equivalent, is in reality no advantage at all. Such is the case with the advantage accruing to the nation with which another is at war, when the property of individuals upon the sea is allowed to pass unmolested. If its riches are increased by freedom of commerce, so are those of its antagonist. The advantages are equal where the circumstances are equal, which, in the majority of cases, they undoubtedly are.

If it be still objected, that there may be cases in which they are not equal, the answer is obvious and incontrovertible. There is no general rule without its exceptions, but partial evil must be admitted for general good. Besides, if the case were very remarkable, it might be excepted from the general rule.

If this were adopted as part of the law of nations, all those questions respecting the maritime traffic of *neutrals*, questions which have been the source of so much troublesome inquiry, so much animosity, and so much mischief, would be immediately at an end. If the traffic of the belligerents, so far as concerned the property of individuals, were free, so would be that of all neutral nations.

Places actually blockaded, that is, surrounded with an hostile force for the immediate purpose of being reduced, either by arms or by famine, would still form exceptions; because the admission of ships into them with

supplies, either of food or munition of war, would be directly at variance with the very object of the blockade.

Law of Nations.

In all other cases, the admission either of provisions or of instruments of war into a belligerent country ought, undoubtedly, upon the principle of utility, not to be disturbed. The benefit, except in rare and remarkable cases, could not be material to the country into which they might enter, nor hence the injury to its antagonist; on the other hand, that antagonist would enjoy the same privilege of the free admission of those commodities, and thus they would be equal in all respects. The inconvenience, however, which would thus be saved to the neutrals—the annoyance of search, the loss by detention, the occasions of quarrel—are known to be evils of no ordinary magnitude.

The desertion of sailors from the ships of a belligerent to those of a neutral has given rise to disputes in one instance only, that of Great Britain and the United States of America. The question to be determined, in laying down the principles of international jurisprudence, is, whether this desertion ought to be considered as constituting a ground for the general right of search; in other words, whether the evil to which a belligerent is exposed by desertion, or rather by that portion of desertion which can be prevented by the right of search, is an equivalent for all the evil which is unavoidably produced by it.

Desertion must take place either from the ships of war of the belligerent, or from its merchant ships.

In respect to ships of war, it is so easy for a belligerent to prevent desertion to neutrals, at least in any such degree as to constitute a great evil, that it would be altogether absurd to speak of it as fit to be compared with the evils arising from the right of search. The only occasions on which ships of war can be exposed to desertion to neutrals, must be those on which they go into a neutral port. But on those comparatively rare occasions, they can so easily take precaution against desertion, that the danger to which they are exposed is hardly worth regarding.

When the sailors belonging to merchant ships transfer their services to the ships of a neutral, it is not to be called desertion. It can only take place in very considerable numbers when seamen's wages in the neutral country are much higher than in the belligerent. The sailor, in this case, leaves his own for another country, only because he improves his situation by so doing. This is a liberty which, as it ought to belong to every body, so it ought not to be withheld from the sailor. If, indeed, any nation thinks proper to forbid any class of its people to leave their country, as England with regard to its artificers, other countries cannot help that; but they ought not to be called upon to lend their aid to such an antisocial regulation, by allowing their vessels to be searched, as security against its infringement. Besides, it is evident that there is a much greater security, arising from the very nature of the case, against the chance of a nation's being, to any considerable degree, deprived of its sailors by any such means. If the sailors go into the neutral country because wages are higher there, a small number only will have gone, when wages, from diminution of the numbers, will begin to rise in the country which they have left, and, from increase of the numbers, will begin to fall in the country to which they have been tempted to repair. When the wages of seamen have thus sufficiently risen in the belligerent country, which they are sure to do if the demand for them rises, the sailors will not only come back from every country in the world, but the sailors of other countries will hurry along with them; and the evil of desertion cures itself.

Only two questions of any great importance appear to remain; that relating to the march of troops, for a hostile purpose, through a neutral country, and that relating to

Law of Nations.

the extent to which the operations of a successful war ought to be pursued.

According to the principles which we have already laid down for regulating the proceedings of a hostile army even in the invaded country, namely, that of committing no plunder, and enjoying the right of market, it appears that the right of passing through a neutral country on similar terms should be refused to no party. This rule, while it holds out equal advantages to all belligerents, admits, less than any other rule, grounds of dispute.

The end, which we have already described as that alone the pursuit of which can render any war justifiable, sufficiently defines the extent to which the operations of a successful war ought to proceed. The end of every justifiable war is to obtain compensation for an injury sustained, and security against the repetition of it. The last point, that of security, alone admits any uncertainty. Nations are apt to exaggerate the demand for security; to require too much; very often unconsciously, from the mere cravings of self-love; sometimes fraudulently, as a cover for ambitious views. As the question, however, respecting what may or may not, in each instance, be sufficient security, is a question of fact, not of law, it must be determined, if determined at all, by a tribunal empowered to take cognizance of the facts.

V.—*Of the Construction of an International Code, and an International Tribunal.—How the Nations might concur in framing an International Code.—How an International Tribunal should be constructed.—Form of Procedure before the International Tribunal.*

We have now, then, laid down the principles by which, in our opinion, the rights of nations, in respect to one another, ought to be determined; and we have shown in what manner those principles should be applied, in order to come to a decision in the most remarkable cases. The minor points it is, of course, not in our power to illustrate in detail; but that will not, we should hope, be difficult, after the exemplification exhibited, and the satisfactory solutions at which we seem to have arrived, of all the more considerable questions which the subject presents.

From what has been shown, it is not difficult to see what would be the course pursued by nations, if they were really actuated by the desire of regulating their general intercourse, both in peace and war, on the principles most advantageous to them all.

Two grand practical measures are obviously not only of primary importance toward the attainment of this end, but are of indispensable necessity toward the attainment of it in any tolerable degree. These are, first, the construction of a code; and, secondly, the establishment of a tribunal.

It is perfectly evident, that nations will be much more likely to conform to the principles of intercourse which are best for all, if they have an accurate set of rules to go by, than if they have not. In the first place, there is less room for mistake; in the next, there is less room for plausible pretexts; and, last of all, the approbation and disapprobation of the world is sure to act with tenfold concentration, where a precise rule is broken, familiar to all the civilized world, and venerated by all.

How the nations of the civilized world might concur in the framing of such a code, it is not difficult to devise. They might appoint delegates to meet for that purpose in any central and convenient place, where, after discussion, and coming to as full an undertaking as possible upon all the material points, they might elect some one person, the most capable that could be found, to put these their determinations into the proper words and form; in short, to make a draught of a code of international law, as effectually as possible providing for all the questions

Law of Nations.

which could arise, upon their interfering interests, between two nations. After this draught was proposed, it should be revised by the delegates, and approved by them, or altered till they deemed it worthy of their approbation. It should then be referred to the several governments, to receive its final sanction from their approbation; but, in the mean time, it should be published in all the principal languages, and circulated as extensively as possible, for the sake of two important advantages. The first would be, that, the intelligence of the whole world being brought to operate upon it, and suggestions obtained from every quarter, it might be made as perfect as possible. The second would be, that the eyes of all the world being fixed upon the decision of every nation with respect to the code, every nation might be deterred by shame from objecting to any important article in it.

As the sanction of general opinion is that upon which chiefly, as we have already seen, such a code must rely for its efficiency, not a little will depend upon the mode in which it is recognised and taught. The recognition should in each country have all possible publicity and solemnity. Every circumstance which can tend to diffuse the opinion throughout the earth, that the people of each country attach the highest importance to such a code, is to themselves a first-rate advantage; because it must be of the utmost importance to them, that all the nations of the earth should behave towards them upon the principles of mutual beneficence; and nothing which they can do can have so great a tendency to produce this desirable effect, as its being generally known that they venerate the rules which are established for its attainment.

If nations, then, were really actuated by the desire of regulating their mutual intercourse upon principles mutually beneficent, they would adopt measures for having a code of international law constructed, solemnly recognised, and universally diffused and made known.

But it is not enough that a code should exist: every thing should be done to secure a conduct conformable to it. Nothing is of so much importance for this purpose as a tribunal; before which every case of infringement should be tried, the facts of it fully and completely explored, the nature and degree of the infringement ascertained; and from which a knowledge of every thing material to the case should be as rapidly as possible diffused through the world; before which also all cases of doubt should regularly come for determination: and thus wars, between nations which meant justly, would always be avoided, and a stigma would be set upon those which justice could not content.

The analogy of the code, which is, or ought to be, framed by each state for regulating the intercourse of its own people within its own territory, throws all the illustration which is necessary upon the case of a tribunal for the international code. It is well known, that laws, however carefully and accurately constructed, would be of little avail in any country, if there was not some organ, by means of which it might be determined when individuals had acted in conformity with them, and when they had not; by which also, when any doubt existed respecting the conduct which in any particular case the law required, such doubt might be authoritatively removed, and one determinate line of action prescribed. Without this, it is sufficiently evident that a small portion of the benefit capable of being derived from laws would actually be attained. It will presently be seen how much of the benefit capable of being derived from an international code must be lost, if it is left destitute of a similar organ. We shall first consider in what manner an international tribunal might be constructed; and, next, in what manner it might be appointed to act.

Law of Nations.

As it is understood that questions relating to all nations should come before it, what is desirable is, that all nations should have equal security for good judicature from it, and should look with equal confidence to its decisions.

An obvious expedient for this purpose is, that all nations should contribute equally to its formation; that each, for example, should send to it a delegate or judge. Its situation should be chosen for its accessibility, and for the means of publicity which it might afford; the last being, beyond comparison, the advantage of greatest importance. As all nations could not easily, or would not, send, it would suffice if the more civilized and leading nations of the world concurred in the design, with such a number of the less considerable as would be sure to follow their example, and would be desirous of deriving advantage from an instrument of protection, which to them would be of peculiar importance.

As it is found by specific experience, and is, indeed, a consequence of the ascertained laws of human nature, that a numerous assembly of men cannot form a good judicatory; and that the best chance for good judicial service is always obtained when only one man judges, under the vigilant eyes of interested and intelligent observers, having full freedom to deliver to the world their sentiments respecting his conduct; the whole of these advantages may be obtained, in this case, by a very effectual expedient. If precedent, also, be wanted, a thing which in certain minds holds the place of reason, it is amply furnished by the Roman law; according to which, a great number of judges having been chosen for the judicial business generally of the year, a selection was made out of that number, according to certain rules, for each particular case.

Every possible advantage, it appears, would be combined in the international tribunal, if the whole body of delegates or judges, assembled from every country, should, as often as any case for decision came before them, hold a conference, and, after mature deliberation, choose some one individual of their body, upon whom the whole duty of judge should, in that case, devolve; it being the strict duty of the rest to be present during the whole of his proceedings, and each of them to record separately his opinion upon the case, after the decision of the acting judge had been pronounced.

It would be, no doubt, a good general rule, though one can easily foresee cases in which it would be expedient to admit exceptions, that the judge, who is in this manner chosen for each instance of the judicial service, should not be the delegate from any of the countries immediately involved in the dispute. The motive to this is sufficiently apparent.

We apprehend, that few words will be deemed necessary to show how many securities are thus provided for the excellence of the judicial service.

In the first place, it seems impossible to question, that the utmost fairness and impartiality are provided for in the choice of the judge; because, of the two parties involved in the dispute, the one is represented by a delegate as much as the other, and the rest of the delegates are indifferent between them. In general, therefore, it is evident, that the sinister interest on the two sides being balanced, and there being a great preponderance of interest in favour of nothing but a just decision, that interest will prevail.

The best choice being made of a judge, it is evident that he would be so situated as to act under the strongest securities for good conduct. Acting singly, he would bear the whole responsibility of the service required at his hands. He would act under the eyes of the rest of the assembled delegates, men versed in the same species of business, chosen on account of their capacity for the service, who could be deceived neither with respect to the

diligence which he might exert, nor the fairness and honesty with which he might decide; while he would be watched by the delegates of the respective parties, having the power of interest stimulating them to attention; and would be sure that the merits or demerits of his conduct would be made fully known to the whole, or the greater part of the world.

The judicatory being thus constituted, the mode of proceeding before it may be easily sketched.

The cases may be divided into those brought before it by the parties concerned in the dispute, and those which it would be its duty to take up when they were not brought before it by any of the parties.

A variety of cases would occur, in which two nations, having a ground of dispute, and being unable to agree, would unite in an application to the international tribunal for an adjustment of their differences. On such occasions, the course of the tribunal would be sufficiently clear. The parties would plead the grounds of their several claims; the judge would determine how far, according to the law, they were competent to support those claims; the parties would adduce their evidence for and against the facts on which the determination of the claims was found to depend; the judge would receive that evidence, and finally decide. All this is so perfectly conformable to the course of pleading, and receiving proof, in the case of suits between individuals, as analysed and explained in the preceding article, that it is unnecessary to be more particular here. If further exposition is required, it will be found upon a reference to the article to which we allude. Decision, in this case, it is observable, fully accomplishes its end; because the parties come with an intention of obeying it.

Another, and a numerous class of cases, would probably be constituted, by those who would come before it, complaining of a violation of their rights by another nation, and calling for redress.

This set of cases is analogous to that, in private judicature, when one man prosecutes another for some punishable offence.

It should be incumbent upon the party thus applying to give notice of its intention to the party against which it is to complain, and of the day on which it means that its complaint should be presented.

If both parties are present when the case comes forward for trial, they both plead, according to the mode described in the preceding article; evidence is taken upon the decisive facts; and if injury has been committed, the amount of compensation is decreed. When it happens that the defendant is not present, and refuses to plead, or to submit, in this instance, to the jurisdiction of the court, the inquiry should notwithstanding go on; the allegations of the party present should be heard, and the evidence which it adduces should be received. The non-appearance of the party defendant should be treated as an article of evidence to prove the truth of its opponent's allegations. And the fact of not appearing should itself be treated as an offence against the law of nations.

It happens, not unfrequently, when nations quarrel, that both parties are in the wrong; and on some of these occasions neither party might think proper to apply to an equitable tribunal. This fact, namely, that of their not applying to the international tribunal, should itself, as stated before, be marked in the code as an international offence, and should be denounced as such by the international tribunal. But even when two offending parties do not ask for a decision from the international tribunal, it is not proper that other nations should be deprived of the benefit of such a decision. If these decisions constitute a security against injustice from one another to the general community of nations, that security must not be al-

Law of Nations.

Law of Nations.

lowed to be impaired by the refractory conduct of those who dread an investigation of their conduct.

Certain forms, not difficult to devise, should be laid down, according to which, on the occurrence of such cases, the tribunal should proceed. First of all, it is evident that the parties in question should receive intimation of the intention of the court to take cognizance of their disputes on a certain day. If the parties, one or both, appeared, the case would fall under one of those which have been previously as above considered. If neither party appeared, the court would proceed to estimate the facts which were within its cognizance.

It would have before it one important article of evidence, furnished by the parties themselves, namely, the fact of their non-appearance. This ought to be considered as going far to prove injurious conduct on both sides. The evidence which the court would have before it, to many specific facts, would be liable to be scanty, from the neglect of the parties to adduce their pleas and evidence. The business of the court, in these circumstances, would be, to state correctly such evidence, direct or circumstantial, as it had before it; giving its full weight to the evidence contained in the fact of non-appearance; and to pronounce the decision which the balance of the evidence, such as it was, might be found to support.

Even in this case, in which the practical effect of a decision of the international court may be supposed to be the least, where neither party is disposed to respect the jurisdiction, the benefit which would be derived would by no means be inconsiderable. A decision solemnly pronounced by such a tribunal would always have a strong effect upon the imaginations of men. It would fix and concentrate the disapprobation of mankind.

Such a tribunal would operate as a great school of political morality. By sifting the circumstances in all the disputes of nations, by distinguishing accurately between the false colours and the true, by stripping off all disguises, by getting at the real facts, and exhibiting them in the true point of view, by presenting all this to the world, and fixing the attention of mankind upon it by all the celebrity of its elevated situation, it would teach men at large to distinguish. By habit of contemplating the approbation of such a court attached to just proceeding, its disapprobation to unjust, men would learn to apply correctly their own approbation and disapprobation; whence would flow the various important effects which those sentiments, justly excited, would naturally and unavoidably produce.

As, for the reasons adduced at the beginning of this article, the intention should never be entertained of supporting the decisions of the international court by force of arms, it remains to be considered what means of another kind could be had recourse to in order to raise to as high a pitch as possible the motive of nations respectively to yield obedience to its decisions.

We have already spoken of the effect which would be produced, in pointing the sentiments of mankind, and giving strength to the moral sanction, by the existence of an accurate code, and the decisions themselves of a well-constituted tribunal.

To increase this effect to the utmost, publicity should be carried to the highest practicable perfection. The code, of course, ought to be universally promulgated and known. Not only that, but the best means should be in full operation for diffusing a knowledge of the proceedings of the tribunal; a knowledge of the cases investigated, the allegations made, the evidence adduced, the sentence pronounced, and the reasons upon which it is grounded.

The book of the law of nations, and selections from the book of the trials before the international tribunal, should form a subject of study in every school, and a knowledge

of them a necessary part of every man's education. In this manner a moral sentiment would grow up, which would, in time, act as a powerful restraining force upon the injustice of nations, and give a wonderful efficacy to the international jurisdiction. No nation would like to be the object of the contempt and hatred of all other nations; to be spoken of by them on all occasions with disgust and indignation. On the other hand, there is no nation which does not value highly the favourable sentiments of other nations; which is not elevated and delighted with the knowledge that its justice, generosity, and magnanimity, are the theme of general applause. When means are taken to make it certain, that what affords a nation this high satisfaction will follow a just and beneficial course of conduct, that what it regards with so much aversion will infallibly happen to it if it fails in the propriety of its own behaviour, we may be sure that a strong security is gained for a good intercourse among nations.

Besides this, it does not seem impossible to find various inconveniences, to which, by way of penalties, those nations might be subjected, which refused to conform to the prescriptions of the international code.

Various privileges granted to other nations, in their intercourse with one another, might be withheld from that nation which thus demeaned itself in a way so contrary to the general interests. In so far as the withholding of these privileges might operate unfavourably upon individuals belonging to the refractory nations, individuals who might be little, or not at all, accessory to the guilt, the effect would be the subject of proportional regret. Many, however, in the concerns of mankind, are the good things which can only be attained with a certain accompaniment of evil. The rule of wisdom, in such cases, is, to make sure that the good outweighs the evil, and to reduce the evil to its narrowest dimensions.

We may take an instance first from trivial matters. The ceremonial of other nations might be turned against the nation, which, in this common concern, set itself in opposition to the interests of others. The lowest place in company, the least respectful situation on all occasions of ceremony, might be assigned to the members of that nation, when travelling or residing in other countries. Many of those marks of disrespect, implying injury neither to person nor property, which are checked by penalties in respect to others, might be free from penalties in respect to them. From these instances, adduced merely to illustrate our meaning, it will be easy to see in what manner a number of considerable inconveniences might, from this source, be made to bear upon nations refusing to conform to the beneficial provisions of the international code.

Besides the ceremonial of other nations, means to the same end might be derived from the law. A number of cases might be found in which certain benefits of the law, granted to other foreigners, might be refused to them. They might be denied the privilege of suing in the courts, for example, on account of any thing except some of the higher crimes, the more serious violations of person or property.

Among other things, it is sufficiently evident that this tribunal would be the proper organ for the trial of piracy. When preponderant inconvenience might attend the removing of the trial to the usual seat of the tribunal, it might delegate for that purpose the proper functionaries to the proper spot.

By the application of the principles which we have thus expounded, an application which implies no peculiar difficulty, and requires nothing more than care in the detail, we are satisfied that all might be done, which is capable of being done, toward securing the benefits of international law.

(J. M.—L.)

Law of Nations.

Law, John.

LAW, JOHN, commonly known by the name of the Projector, was the eldest son of William Law, and was born at Edinburgh in the month of April 1671. His father followed the profession of goldsmith or banker, with so much success, that he was enabled to purchase the lands of Lauriston and Randleston, which afterwards descended to his son. The latter was educated at Edinburgh, where he is said to have made some progress in literature; but the bent of his genius having led him to study arithmetic and geometry, he attained such proficiency in these branches as to be able to solve with facility the most intricate problems; and he likewise made himself master of algebra. The principles of public and private credit, the state of trade and of manufactures, the theory and practice of taxation, and other matters connected with political economy, also engaged his attention; and the accession of knowledge resulting from these inquiries laid the foundation of his future eminence. But he soon became noted as a man of pleasure as well as of study. Having lost his father before he had completed his fourteenth year, he was thus left at an early age without paternal control; and as the graces of a naturally handsome person were improved by the acquisition of external accomplishments, Jessamy John, or Beau Law, as he was indifferently called by his companions, addicted himself to the practice of all games of chance, skill, and dexterity, and appears to have engaged in other pursuits of a still more questionable character. In 1694 he visited London, where his wit and accomplishments procured him admission into the first circles, whilst his extravagance speedily involved him in difficulties. At this time he was noted for his propensity to deep play, and for his gallantries amongst women. By the former, he injured his fortune; in consequence of the latter, he narrowly escaped an ignominious end. An intrigue which he had with a Mrs Lawrence proved the occasion of a quarrel between him and one Mr Edward Wilson; a hostile meeting ensued, and Mr Law killed his antagonist on the spot. He was immediately apprehended, and brought to trial at the Old Bailey, on a charge of murder; and being found guilty, received sentence of death. Upon a representation of the case to the crown, however, Law obtained a pardon; but an appeal being lodged by a brother of the deceased, he was detained in the King's Bench Prison. This appeal was brought before the Court of King's Bench in Trinity-term 1694: and as the exceptions taken on the part of Law were overruled by the court, the latter, judging it not prudent to await the result, found means to escape from prison,¹ and retired to the Continent.

Law resided for several years abroad, first at Paris, where he acquired great dexterity in all games of chance, and afterwards at Genoa and Venice. One cause assigned for his leaving Paris, was his eloping with Lady Catherine, third daughter of Nicholas, Lord Banbury, and wife of Mr Senor, or Seinour. His success in play was so great, that he is said to have acquired L.20,000. At Venice his attention was first directed to the subject of paper-money and banking; but failing in his application, during the reign of William III., to return to England, he proceeded to Amsterdam, and made himself practically acquainted with the Dutch system of banking. An anonymous work, by William Paterson, entitled, *Proposals and Reasons for Constituting a Council of Trade*, printed at Edinburgh in 1701, at an interval of fifty years, was republished at Glasgow, and the name of Law given as its author, without any authority.

Being dated from Edinburgh, 31st December 1700, Law's Law, John, biographers have concluded that he must have then returned to Scotland; but the work was unquestionably written by Paterson, known as the founder of the Bank of England, and of the Darien Scheme. Five years later, however, Law, having secured the interest of several persons of distinction, offered to the Scottish parliament, in 1705, a plan for removing the difficulties under which the kingdom then laboured from the scarcity of specie, and the stoppage of payments by the bank; and, with a view to further his object, he published a work, entitled, *Money and Trade considered, with a Proposal for supplying the Nation with Money*, which appeared at Edinburgh the same year. His "proposal" was, that commissioners, to be appointed by an act, under the control of parliament, should be empowered to issue notes, either in the way of loan, at ordinary interest, or upon landed security; the debt, however, not to exceed half, or at the most, two-thirds, of the value of the land; or upon land-pledges, redeemable within a certain period, to the full value of the land; or, lastly, upon sale irredeemably to the amount of the price agreed upon. Paper-money, thus issued and secured, would, he conceived, be equal in value to gold and silver money of the same denomination, and might even be preferred to these metals, as not being, like them, liable to fall in value. But this scheme, though supported by the united weight of the court party, and of that called the *squadron*, headed by the Duke of Argyll and the Marquis of Tweeddale, was rejected, as the parliament on the 27th of July 1705 resolved, "that the forcing any paper credit by an Act of Parliament was unfit for this nation;" and, likewise, that "it was an unfit expedient for this nation, that the current specie within the kingdom should be raised above for what it passes at present." The rejection of the plan was occasioned by an apprehension, that if it were adopted all the estates of the kingdom would thereby be brought to a complete dependence upon the government. He also failed in a final application to Queen Anne for a pardon of the sentence given against him for Wilson's murder in 1694, which precluded his return to England.

Mr Law therefore resolved to abandon his native country, and to try his fortune abroad. He resided some time at Brussels, where he became noted for extraordinary success at play; and in two excursions which he made to Paris, his good fortune at the gaming-table became still more conspicuous. Having visited the principal cities of Italy, he continued the same career, playing at all sorts of games, and betting and speculating in the public funds and banks, with uninterrupted success; insomuch that, in the year 1714, he was worth upwards of L.110,000 sterling. During these rambles, Law, having the advantage of a graceful figure and an insinuating address, was everywhere well received by persons of the highest quality. At Florence he became acquainted with the Duke de Vendôme, whom he had the honour to oblige with the loan of a considerable sum of money. At Neuchâtel he obtained access to the Prince of Conti, to whom he imparted some of his financial projects. During a short residence at Turin, he communicated to Victor Amadeus, King of Sardinia, a scheme for aggrandizing his territories, of the same nature as that which he afterwards proposed to the Duke of Orleans; but the prudent monarch declined embarking in so perilous an adventure, observing to the projector, that his dominions were too small for the execution of so great a design, and that

¹ In the *London Gazette* of Monday, 7th January 1695, a reward of fifty pounds was offered for the apprehension of "Captain John Law, a Scotchman, lately a prisoner in the King's Bench for murder," who is described as "a very tall, black, lean man, well shaped, above six foot high, large pock-holes in his face, big high nosed, speaks broad and loud." This description, which conveys no very favourable idea of Law's personal appearance, and differs from his real portrait, is supposed by Mr Wood to have been drawn up with a view to facilitate his escape. The prefix of "Captain," which is otherwise a good travelling title, may also, perhaps, be explained on the same hypothesis.

Law, John. France was the proper theatre for such speculations. "If I know the disposition of the people of that country," added Victor Amadeus, "I am sure they will relish your schemes; and, therefore, I would advise you to go thither without delay."

Law took the advice which was thus given him, and returned to Paris, where he arrived in 1714, not long before the death of Louis XIV. He was more favourably received than on the occasion of his former visits, when he appears to have been regarded as a mere adventurer; and soon gained the confidence of the Duke of Orleans to such a degree, that he was not only admitted to the convivial parties of the regent, but even nominated one of his counsellors of state. At this time the French finances were in the greatest disorder, indeed in a situation accounted desperate; the nation was burthened with an immense load of debt, contracted during the expensive wars of Louis XIV.; and the people groaned under the intolerable pressure of the taxes which had been imposed for payment of the interest. All industry was thus checked, and trade in a manner annihilated; manufactures, commerce, and navigation, had almost ceased; the merchant and the trader were reduced to beggary, and the artificer was compelled, for want of employment, to leave the kingdom. In a word, the state of affairs was such, that it had been debated in council, and actually proposed to apply a sponge to the debt, and to seek relief by means of a national bankruptcy. The proposal, however, was rejected by the regent, and a commission appointed to inquire into the claims of the state creditors, and endeavour to introduce some degree of order into the public finances. At this calamitous crisis, when the surplus of the public revenue, after payment of the interest of the debt, was found insufficient to defray the necessary expenses of the civil government, Law came forward with his favourite nostrum or panacea, and proposed to liquidate the debt, by establishing a bank for issuing notes secured upon landed property, and on the unalienable impledgement of all the royal revenues. The project seems to have been approved of, but as the conjuncture was thought unfavourable for risking so bold an experiment, his application proved ineffectual. Nothing discouraged, Law requested and obtained permission to establish a private bank, to consist entirely of funds advanced by himself, and others who chose to embark in the undertaking. The letters-patent, which are dated the 2d and 20th of May 1716, specify the principles upon which the bank had been established, as well as the regulations according to which it was to be conducted. The scheme promised success, and, in fact, the General Bank of Law and Company had acquired great credit, when, in December 1718, it was dissolved by an *arrêt* of the regent, who, observing the advantages resulting from the establishment, resolved to take it into the hands of government; a resolution which could not be very agreeable to the founder and his associates in the enterprise. Law, however, was named director-general of the Royal Bank, in which his own had merged; and branches were established at Lyons, Rochelle, Tours, Orleans, and Amiens.

Law now began to develop the stupendous project he had long meditated, and which afterwards became so well known to all Europe, under the name of the Mississippi System. This scheme was nothing less than the vesting of the whole privileges, effects, and possessions of all the foreign trading companies, the great farms, the mint, the general receipt of the king's revenues, and the management and property of the bank, in one great company, who, having thus in their hands all the trade, taxes, and royal revenues, might be enabled to multiply the notes of the bank to any extent they pleased, doubling or even tripling at will the circulating medium of the kingdom, and, by the immensity of their funds, possessed of a power to carry the foreign trade and the improvement of the colonies to a

height altogether unattainable by other means. This monstrous and impracticable monopoly was approved of by the regent, and by letters-patent a commercial company was established, under the name of the Company of the West; to which was at the same time granted the whole province of Louisiana, a country watered throughout its whole extent by the Mississippi, from which the project accordingly took its name. The scheme was well calculated to entrap the unwary and to seduce the speculative. Of this company 200,000 actions or shares were issued, at 500 livres each, and the subscriptions were made payable in a depreciated paper-currency, called *billets d'état*, which, however, in the subscriptions, was taken at its full value. This could not fail to operate as a tempting bait to the holders of these billets or notes to lay them out in the purchase of shares, especially since the depreciation amounted to between sixty and seventy per cent. The company thus became creditors of the king to the extent of a hundred millions of livres, the interest of which sum was fixed at the rate of four per cent.

Law, who had now advanced high in the regent's favour, was of course named director-general of the Company of the West, and thus intrusted with the development of his own stupendous project. Louisiana having been represented as a region abounding in gold and silver, and possessing a fertile soil capable of the highest cultivation, the actions or shares were bought up with the greatest avidity; and such was the rage for speculation, that the unimproved parts of the colony were actually sold for 30,000 livres the square league. In pursuance of the scheme, the farm of tobacco was made over to the company at an advance of rent exceeding two millions of livres. Soon afterwards they acquired the charter and effects of the Senegal Company; and this was succeeded by a still more important acquisition, namely, the exclusive privilege of trading to the East Indies, China, and the South Seas, together with all the possessions and effects of the China and India companies, now dissolved, upon the condition of liquidating all just claims against them. Upon this occasion, the Company of the West assumed the title of Company of the Indies; and 50,000 new shares were ordered to be constituted, at 550 livres each, payable in coin. The price of actions quickly rose to 1000 livres each. On the 25th of July 1719, the mint was made over to this company for a consideration of fifty millions of livres, to be paid to the king within fifteen months; on the 27th of August following, the regent took out of the hands of the farmers-general, and made over to them, the great farms, for which they agreed to pay an advance of rent of three millions and a half of livres; and, on the 31st of the same month, they also obtained the general receipt or collection of the other branches of the king's revenue. Having acquired all these grants, and thus concentrated in themselves not only the whole foreign trade and possessions of France, but also the collection and management of the royal revenues, they promised an annual dividend of 200 livres on every share; the price of actions instantly rose in the market to 5000 livres; and the public ran with such eagerness upon the last creation of stock, that nearly double the requisite sum was subscribed, whilst the greatest interest was exerted, and every stratum put in practice, to secure places in that subscription. The frenzy now became general. A rage for the acquisition of shares in the India Company seized and infatuated all ranks in the kingdom. Clergy and laity, peers and plebeians, princes and peasants, statesmen and magistrates, nay, even ladies, all, in short, who either had or could procure money for the purpose, turned stockjobbers, outbidding each other with such avidity, that, in November 1719, the price of shares rose to above 10,000 livres, or (when the depreciation of the *billets d'état* is taken into account) more than sixty times the sum they originally sold for. Nothing was talked of but actions; every place echoed with Missis-

Law, John. sippi and Quinquempoix.¹ All classes appeared to have but one object, one pursuit. Mechanics laid aside their work, tradesmen forsook their shops, and persons of all grades neglected their professions or employments, to embark in this new occupation; whilst even the few who observed some degree of moderation, showed by their conduct how little concern they took in affairs foreign to the Mississippi scheme.² The delirium had reached its culminating point.

Mr Law now blazed a meteor of unequalled splendour. He possessed the ear of the Duke of Orleans; he was almost adored by the people, ever ready to worship at the shrine of the idol of the hour; and he was surrounded by princes, dukes, peers, marshals, and prelates, who all courted his friendship, and even seemed ambitious of his patronage. Nobles were content to wait in his ante-chambers, like the meanest subjects; and ladies of the highest quality employed every artifice, sometimes at the risk of their necks, to attract his passing notice.³ The property which he acquired was immense. He purchased no less than fourteen estates with titles annexed to them, and amongst these the marquisate of Rosny, which had belonged to the illustrious Sully, the friend and minister of Henri IV. About this period, too, a free pardon for the murder of Mr Wilson was conveyed to him from England; and Edinburgh, proud of having produced so great a personage, transmitted to him the freedom of the city in a gold box. By his abjuration of the Protestant religion, the only obstacle which stood in the way of his advancement to the highest offices in the state was soon afterwards removed; and, on the 5th of January 1720, he was appointed comptroller-general of the finances. A few days previous to this, the Academy of Sciences had elected him one of its honorary members; and the flattering incense of poetry was offered up at the same shrine with the homage of an infatuated people. Thus the astonished world beheld an obscure foreigner, of doubtful reputation and questionable character, rise in a few months from a private condition to the high station of prime minister of France, and govern for a time, with almost absolute power, one of the greatest and most enlightened nations of Europe. It might well be said of him, *Tollitur in altum ut casu graviore cadat*.

But after having raised himself to such an unexampled eminence, Law at length fell a sacrifice to the intrigues of the other ministers, who, partly from envy, and partly from apprehension, combined with ignorance, undermined the insecure fabric he had reared, and thus precipitated its fall. The credit of the bank and of the India Company had attained its height in November 1719, when shares of the latter sold for more than 10,000 livres each, and money was so abundant in the former that the directors agreed to lend any sum upon proper security at two per cent. But amidst the general delirium, there were symptoms which evidently betokened an approaching revulsion. The most alarming of these was a constant drain of specie from the bank, either for the purpose of being hoarded or sent

abroad. Astonished at their exorbitant gains, the original proprietors of the company thought only of converting their shares into gold, and realizing the fortunes which they had so suddenly acquired; and it was computed that not less than 500 millions of livres, the property of persons of this description, had been sent out of France. To avert the danger which thus threatened the system, several edicts were issued early in 1720, by which payments in specie were restricted to small sums, and the standard of the coin was kept in continual fluctuation, whilst bank-notes were declared to remain invariable, and rents, taxes, and customs were made payable in notes. But what crowned all was the edict of the 27th February 1720, prohibiting individuals, as well as secular or religious communities, from having in their possession more than 500 livres in specie, under the penalty of a fine, and confiscation of all sums found exceeding that amount; a measure which could scarcely fail to sow distrust in the bosom of families, and to excite alarm in the public mind. Still the delusion prevailed. On the 23d of February, a few days before the publication of this edict, the Royal Bank had been incorporated with the company, and the king not only remained guarantee of the bank-notes, but gave up to the company all the profits made by the bank since December 1718, when the government had taken it into its own hands. Meanwhile, the manufacture of notes proceeded with so much activity, that, by the 1st of May 1720, paper-money had been fabricated to the amount of more than 2600 millions of livres, or nearly L.110,000,000 sterling; whilst the specie in the kingdom was estimated at only 1300 millions of livres, or about L.52,000,000 sterling. In this state of matters, Cardinal Dubois and M. D'Argenson represented to the regent that it had become necessary to equalize the proportion between the notes and the coin, either by reducing the value of the one to the extent of a half, or by doubling that of the other.

This extraordinary point was debated in council, where it was opposed by some of the members, amongst whom was the comptroller-general, who strenuously contended for letting matters remain as they were; but the majority being in favour of the proposition for lowering the value of the paper, it was decided accordingly; and, on the 21st of May 1720, an edict was issued, which, contrary to all sound policy, and even to the most solemn stipulations, reduced the value of the company's bank-notes one-half, and fixed their actions or shares at 5000 livres. By this unjustifiable and fatal step, the whole paper fabric was destroyed in an instant, the notes lost all credit, and next day a man might have starved with 100 millions of paper money in his pocket. The consternation with which all ranks were seized was soon converted into rage, and it became necessary to station troops in different parts of the capital, to prevent the consequences to be apprehended from the fury and despair of the populace. Disorder and confusion reigned everywhere; seditious and inflammatory libels were posted up and distributed; and the life of the regent himself was

¹ The street where the stockjobbing was at first carried on.

² The unexampled rise in the price of actions enabled obscure and humble individuals to acquire at once princely fortunes; and many amusing anecdotes are told of persons thus suddenly raised to affluence. A footman having realized a large sum, provided himself with a carriage; but the first day it drew up at his door, obeying the instinctive habit of his calling, he, instead of stepping into the vehicle, mounted up to his old station behind it. Another of the same fraternity, who had obeyed the like familiar impulse, endeavoured adroitly to cover his mistake by pretending that he got up merely to see if there was room at the back for two or three more lacqueys, whom he was resolved to hire instantly. Law's coachman had made so great a fortune that he asked a dismissal from the service of his master, which was granted, on condition of his procuring another as good as himself. Cook-maids and waiting-women appeared at the opera, bedizened with jewels and finery; many who had not a dozen livres in the world suddenly "tumbled from a garret into a carriage;" and the son of a baker at Toulouse, being desirous of having a superb service of plate, purchased the contents of a goldsmith's shop for 400,000 livres, and sent them home to his wife, with orders to set them out properly for supper. In a word, property underwent a new and most grotesque distribution.

³ The regent's mother asserts, in one of her letters, that "si Laws le vouloit, les femmes Françaises lui baiseroient la derrière;" a strong expression, certainly, but one which shows that all ideas of delicacy, or even decency, were absorbed by the cupidity and avarice which had taken possession of the public mind.

Law, John. threatened.¹ Some conception may be formed of the distress of the people, when it is considered that at the time when the bank thus stopped payment, and the value of paper money instantly sunk to zero, not less than 2,235,085,590 livres, or upwards of L.90,000,000 sterling in notes, were in circulation. Law was, of course, peculiarly obnoxious to popular odium, which he endeavoured in vain to allay by resigning into the hands of the regent his office of comptroller-general, on the 29th of May; but, though several times exposed to imminent danger, from the vengeance both of the parliament and the people, he remained in France until towards the close of the year 1720, when he withdrew to Brussels; and soon afterwards his whole property was confiscated, and his brother William sent to the Bastille.

Law arrived at Brussels on the 22d of December 1720, and, after waiting there for some time, in the vain expectation of being recalled to France, set out for Venice, which he reached early in January 1721; he then visited other places on the Continent, and, in October, arrived in England, for the ostensible purpose of pleading the king's pardon. He was at first well received, and visited by persons of distinction; but when it was discovered that the fallen financier was in a state almost bordering upon destitution, his friends began to fall off, and, of those who had known or perhaps courted him in his day of power, he could find none good-natured enough to lend him a thousand pounds. In a letter addressed to Mrs Howard, afterwards Countess of Suffolk, he calls that lady his "only friend;" an avowal which affords a striking instance of the instability of fortune, power, and friendship. After residing some years in England, this extraordinary man returned once more to the Continent, and closed his chequered career at Venice, where, on the 21st of March 1729, he died in a state but little removed from indigence, in the fifty-eighth year of his age. Lady Catherine Knollys, with whom Law had eloped, as formerly mentioned, but whom he subsequently married, survived him several years, having died in 1747. Soon after his death appeared the following epitaph, the point of which reminds us of the bitter jests which appeared upon the occasion of his fall:—

Ci git cet Ecossois célèbre,
Ce calculateur sans égal,
Qui, par les règles de l'algèbre,
A mis la France à l'hôpital.

Even if it had not been interrupted by the edict of the regent, Law's project was too insecure in principle to have proved permanent. The favourite maxim inculcated by Law, and upon which his whole fabric of the Mississippi system was reared; namely, that the power and prosperity of a nation increase in proportion to the quantity of money circulating therein, and that, as the richest nations have not specie sufficient to afford full employment to their inhabitants, this defect may be supplied by paper credit; involves a dangerous fallacy, even in the most restricted view that can be taken of its application, inasmuch as it implies

that paper money may be issued with advantage to an almost unlimited extent, upon general security; and that its credit, or, in other words, its value, may thus be maintained without its being rendered convertible at pleasure into cash. But all experience has proved that this is absolutely impossible. When paper is in excess, in comparison with the total amount of gold and silver currency, it necessarily becomes depreciated; the prices of commodities experience a corresponding rise; the nominal value of the precious metals is increased in proportion to the amount of the depreciation, of which this increase is the only measure, and they disappear from circulation. All existing contracts and obligations are disturbed; debtors benefited at the expense of creditors; a spirit of reckless speculation and adventure is thus engendered; and, after a time, the crisis of revolution and ruin arrives. Whenever the quantity of money in circulation is too great in proportion to the total amount of commodities to be circulated by it, depreciation is the necessary consequence, or, in other words, a proportional rise in the price of commodities. Money has no creative power, as Law seems all along to have imagined, and can never be in excess without endangering "the power and prosperity" of the nation where this is the case. His whole system, therefore, was built upon a sandy foundation, and, even if it had received no rude or sudden shock, would have fallen to pieces from its own insecurity and instability. At the same time, there is much truth in an observation of Mr Burke, in his *Reflections on the French Revolution*. "It is not true," says he, "that Law built solely on a speculation concerning the Mississippi; he added the East India trade, he added the African trade, he added the farms of all the farmed revenue of France; all these unquestionably could not support the structure which the public enthusiasm, not he, chose to build on these bases. He laid the best foundation that he could, perhaps the best which, in the circumstances, it was possible to lay; but the nation went suddenly mad, an event which he could scarcely have foreseen; the company was hurried onwards by the general frenzy; and when the delirium had reached its height, the regent was advised to issue the fatal edict, which levelled the whole fabric to the dust.

(See *Œuvres de Law*, passim; *Histoire du Système des Finances*, tom. i.; Pollnitz, *Mémoires*; Massillon, *Mémoires de la Minorité de Louis XV.*; *Mémoires de la Régence de M. le Duc d'Orléans*, tom. i.; Richelieu, *Mémoires*, tom. iii.; Voltaire, *Siècle de Louis XV.*; Chalmers's *Biog. Dict.*, art. "Law;" Wood, *Life of John Law of Lawriston*, Edinburgh, 1824.) (J. B—E.)

LAW, Edmund, Bishop of Carlisle, was born at Cartmel, in Lancashire, in 1703. After attending school at Cartmel, and afterwards at Kendal, he finished his education at St John's College, Cambridge, and was soon after elected a fellow of Christ College. While residing at Cambridge, he published a translation of Archbishop King's *Essay on the Origin of Evil*; and this raising a controversy between him and Dr Clarke, led soon afterwards to the publication of his *Inquiry into the Ideas of Space, Time, &c.* To

¹ Even in this season of calamity, the French exemplified the indestructible gaiety of their national character, by sporting with their own misfortunes in jests and epigrams. The following hebdomadal record is, perhaps, unique amongst *jeux d'esprits*.

Lundi j'achetai des actions;
Mardi je gagnai des millions;
Mercredi j'arrangeai mon ménage;
Jeudi je pris un équipage;
Vendredi je m'en fus au bal;
Et Samedi à l'hôpital.

The Abbé, afterwards Cardinal, de Tencin, having had the principal share in Mr Law's conversion, a service for which he was rewarded by the bishopric of Grenoble, is thus addressed by a malicious epigrammatist:—

Foin de ton zèle séraphique,
Malheureux Abbé de Tencin!
Depuis que Law est Catholique,
Tout le royaume est Capucin.

Law,
William
||
Lawn.

this is added a valuable dissertation by Waterland, containing one of the happiest refutations of Clarke's *a priori* demonstration. His edition of Stephen's *Thesaurus* was printed about the same time. In 1737 the University presented him with the living of Graystock, in Cumberland; and to this were added in 1743 the archdeaconry of Carlisle, and the living of Salkeld, a village on the River Eden. Living in retirement at this village, he wrote *Considerations on the Theory of Religion*, with *Reflections on the Life and Character of Christ*. In 1756, upon his succeeding Dr Keene as master of Peterhouse, Cambridge, he resigned his archdeaconry, and in 1760 became principal librarian of the university, and afterwards professor of casuistry. In a few years more, honours came rapidly upon him. He was presented with the archdeaconry of Staffordshire, and a prebend in the church of Lincoln. To a stall, obtained in 1767 in the church of Durham, was added in the following year, through the recommendation of the Duke of Grafton, the bishopric of Carlisle. Law had chosen Locke for his master in philosophy; and in 1777 he published an edition of that philosopher's works in 3 volumes with a preface and a life of the author. He died at Rose Castle, his episcopal residence, in 1787, in his eighty-fourth year. Bold and independent in speculation, and tenacious of his own dogmas, Law was still tolerant of the opinions of his opponents, and treated them with respect and candour. His openness to conviction was shown in the important alterations he made in the second editions of his two principal works. Among other peculiar tenets, he holds that without Divine interposition the dead would continue for ever in that state of insensibility which is the result of the fall. In disposition he was cheerful and contented; but his bashfulness and his fondness for literary ease, rendered him too inactive and too facile for his high position in the church.

LAW, William, a well-known religious author, was born at King's Cliff, Northamptonshire, in 1686. He entered Emmanuel College, Cambridge, in 1705; and, with the intention of taking orders, passed through the necessary degrees. He was elected a fellow in 1711, and took the degree of M.A. in the following year. On the accession of George I. he refused to take the prescribed oaths and declaration, and in consequence vacated his fellowship in 1716. After officiating for some time as a curate in London, he went to reside at Putney as tutor to the father of Gibbon the historian. It is not known how long he continued in that situation; but it is certain that he left it about 1740, and retired, along with Hester Gibbon, his ward's sister, and another lady, to his birthplace, for the purpose of leading a retired and charitable life. There he had founded, in 1727, an hospital and a school. After a twenty years' residence, he died on the 19th of April 1761, in the seventy-fifth year of his age.

Law's character is clearly indicated by his published works. It is thus pointedly described by Gibbon in his *Miscellaneous Works*:—"In our family he left the reputation of a worthy and pious man, who believed all that he professed, and practised all that he enjoined."

His works extend to 9 volumes octavo, embracing sixteen treatises and a collection of letters. The most popular are the *Serious Call to a Devout and Holy Life* and the *Practical Treatise upon Christian Perfection*. To the former Dr Johnson attributed his having been led to think earnestly about religion. The *Three Letters to the Bishop of Bangor* are, perhaps, the most powerful of his productions, and very valuable as specimens of a high style of controversy comparatively rare in any language. His *Reply to Mandeville's Fable of the Bees* has been lately republished in a separate form, with an *Introductory Essay*, by F. D. Maurice.

LAWN, fine linen or cambric. See LINEN.

LAWRENCE, SIR THOMAS, a celebrated English painter, was born at Bristol, on the 13th of April 1769. His father, who kept an inn, first in Bristol, and afterwards in Devizes, made some pretensions to literary taste, and was in the habit of reciting poetry; an accomplishment which his son acquired at a very early age, as well as that of taking likenesses with striking fidelity. One of the earliest instances recorded of young Lawrence's genius is to be found in an incident which occurred to Lord and Lady Kenyon, some years previous to the time when the former was elevated to the peerage. Happening to remain for a day at the inn of the elder Lawrence, they were introduced by Boniface to his son, who, he said, "although then only in his fifth year, could recite them poetry or speeches, or take their likenesses." The visitors agreed that the boy's skill with the pencil should be put to the test; and the future president having been lifted on the table, and seated in an arm-chair, took their likenesses with a rapidity, a spirit, and a correctness, which astonished them. With the exception of a few lessons in Latin and French, obtained through a private channel, all the education which young Lawrence received, he acquired between his sixth and eighth year; but his was a mind capable of educating itself, and long ere the young artist attracted public attention, he had treasured up more than an ordinary stock of knowledge. But drawing, particularly taking likenesses, chiefly occupied his attention until he was ten years of age, when he began of his own accord to attempt original compositions of the highest class. The subjects which he chose were of the most ambitious description, such as Peter denying Christ, Haman and Mordecai, and the like. His fame as an artist now spread amongst the families of distinction in the surrounding counties; and not long afterwards, the Honourable Daines Barrington noticed him in his *Miscellanies*, as a striking instance "of early genius in children." The elder Lawrence having failed in business, removed to Bath, where he placed his son for some time with a celebrated crayon painter, under whom he made surprising progress. At this time he executed, at half a guinea each, likenesses of the fashionables of Bath; and this initiatory exercise in drawing individuals in high life, arrayed in their gay and elegant costume, had, doubtless, considerable influence in forming the style of the artist, and preparing him to become the painter of patricians. He now numbered amongst his warm admirers and patrons persons of rank and fortune; but the most remarkable incident in his early career, was his receiving the great silver pallet from the Society of Arts, with a present of five guineas. These marks of distinction were conferred upon him for executing in crayons the Transfiguration of Raphael, when he was only thirteen years of age. His large crayon drawings became in great request; and in Oxford, Salisbury, and other places which he visited, he obtained considerable employment for his pencil. When in his sixteenth year, he conceived a strong desire to appear upon the stage; but the remonstrances of his friends induced him to abandon this project; and about a year afterwards, he made his first attempt in oil painting. In 1787 he removed to London, where he availed himself of the public institutions for instruction in his art, and commenced that career which terminated so triumphantly. He was received at the house of Sir Joshua Reynolds, and encouraged by the great head of the English school of art. His admission as a student at the Royal Academy, and his first appearance in the exhibition at Somerset House, soon followed his arrival in the metropolis. Each succeeding year he increased the number of the performances which he sent in: and his reputation growing apace, he was elected an Associate of the Royal Academy on the 10th of November 1791. The death of Sir Joshua Reynolds in 1792 opened up a fair field of competition for aspiring genius; and although

Lawrence. Mr Lawrence was then only in his twenty-third year, it soon became apparent that he was destined to bear away the palm from the most gifted artists with whom he had to contend. The Dilettanti Society unanimously chose him as their painter in the room of Sir Joshua; and his Majesty George III. also appointed him to succeed the deceased president, as his principal painter in ordinary. On the 10th of February 1794, Mr Lawrence was elected a royal academician; and employment now flowed upon him from all quarters. He made the most rapid progress in his profession, and his reputation grew steadily until he came to be generally considered as the first portrait-painter of the age. An enumeration of the works of this description which he executed would comprehend all the rank, fashion, and intelligence which distinguished the times in which he lived, including those of most of the crowned heads of Europe. The royal family, the nobility and gentry, distinguished men of letters and statesmen, actors and actresses, all sat for their portraits to Lawrence. It may be justly said of him as it was said of Sir Joshua Reynolds, that "he painted three generations of beauties." In 1815 the Prince Regent conferred on him the honour of knighthood; and in 1818, at the request of the same illustrious individual, he was induced to proceed to Aix-la-Chapelle, to take likenesses of the most distinguished statesmen who had there assembled for diplomatic purposes. Having executed his mission at Aix-la-Chapelle, Sir Thomas proceeded to Vienna, and thence to Rome, where he had an opportunity of contemplating, for the first time, the great masterpieces of ancient art. During the whole of his residence on the Continent, he was received by the sovereigns of the different countries he visited, and entertained with marked distinction; and the propriety and elegance of his deportment made an impression highly favourable to his character as an English artist and gentleman. After an absence of eighteen months he returned to England; but, before reaching his native country, he had been unanimously elected to succeed Mr West as president of the Royal Academy; and this office he continued to hold till his death, which took place on the 7th of January 1830.

In portrait-painting, the branch of art which he made his profession, Sir Thomas Lawrence was the most distinguished artist of the day. He was one of the few English painters who attained a proficiency in their art before visiting Italy, or without studying the old masters; a circumstance which must be attributed to his strong native genius and exquisite taste. The distinguishing characteristics of his style was the power of conveying a faithful resemblance, with, at the same time, a singularly delicate sense of beauty, grace, elegance, and dignity. An able writer thus speaks of him:—"No painter who ever lived seemed to have dived more deeply into individual character, as conveyed by the conformation of the visage, and the expression of the features; and none knew more skilfully how to avail himself of the changeful appearances which they betrayed in those conversations which were dexterously introduced during the sitting, and which destroyed or relaxed a rigidity of muscle assumed on such occasions, and which frequently baffles the utmost ingenuity of the artist. In his female portraits (the great test of talent) he had more grace and a greater variety of attitude than Vandyke, although he certainly did not equal him in colouring. It is a general opinion, also, among painters, that he had less nature and less breadth than Sir Joshua Reynolds; and that opinion is probably well founded. Sir Thomas, especially, in the latter periods of his practice, exhibited more detail in his portraits, and appeared to paint with a smaller pencil, than his illustrious predecessor, who, in his effects of light and shade, seemed to take Correggio as his model. The hair in Sir Thomas's pictures was painted in fine masses, in a way peculiar to himself; and his eyes, to the splendour of

which he sometimes made great sacrifices, were divine. Lawrence, The late Mr Fuseli, who was by no means a thorough-going admirer even of Sir Thomas, has been heard to say of him, 'But he paints eyes better than Titian.'

His drawing was admirable, and some of his chalk sketches are considered by the best judges as fine as Michael Angelo or Raffaele could have executed. Sir Thomas did not confine himself to portrait-painting alone, but executed paintings of a far higher order of art. Of these it has been observed by Mr Westmacott, "His illustrations of Cato, Coriolanus, and Hamlet, may be considered historical works, and examples of his creative genius, possessing a vigour of imagination, a propriety of sentiment, a breadth and chasteness of composition worthy to be ranked with the classical and distinguished efforts of the sixteenth century; whilst his more comprehensive powers were displayed in the admirable picture of Satan: all eminent proofs that he possessed talents equal to the accomplishment of the highest designs in the art." In private life Sir Thomas Lawrence was most exemplary, being kind and liberal to artists, and ready to encourage rising merit. In discharge of his duties connected with the high station which he filled in relation to the academy, he displayed unremitting diligence and zeal; "And no man," says an academical, "died with better claims to the respect of his brother members." (J. F. S.)

LAWRENCE, a manufacturing town of the United States of North America, Essex county, Massachusetts, is situate on the left bank of the Merrimac, 26 miles N. of Boston, and forms the centre of a network of railroads communicating with Lowell, Newburyport, Boston, and other places of importance. Although founded but recently, Lawrence has become one of the chief manufacturing towns in New England, in consequence of the great water-power it derives from the Merrimac. In 1845 the Essex Commercial Company constructed a dam of masonry across this stream, by which a fall of 28 feet was obtained for the whole river. From this dam a canal, from 60 to 100 feet broad, 12 feet deep, and more than a mile long, conducts the water to the various factories situate between it and the Merrimac. The town proper, which is laid out between the latter and a small tributary called the Spicket, has in its centre an open common of 17½ acres in extent, and contains a town-house, gaol, several churches and schools, and a literary institute. The inhabitants are almost all employed in the various factories in the town, some of which are of great size, and one, the Pacific, is said to be the largest in the world. The building has seven storeys, and its flooring covers 16 acres, while the consumption of cotton within its walls amounts to 1,500,000 lb. yearly, and of wool to the third of that amount. It gives employment to about 2000 persons. The manufactures of the town comprise woollen, linen, and cotton goods of various kinds. Incorporated, 1847. Pop. (1848), 6000; (1850), 8283; (1855), about 14,000.

LAWRENCE, St, GULF, an inlet of the Atlantic Ocean, British North America, having Newfoundland on the E., Labrador, Lower Canada, and New Brunswick on the N. and W., and Nova Scotia and Cape Breton on the S.; extending from N. Lat. 46. to 51. 30., and W. Long. 58. to 65. It communicates with the ocean by three channels, the principal of which is between Cape Breton and Newfoundland, 48 miles in width at its narrowest part. The other two channels are much narrower; the Straits of Belle Isle, between the N. extremity of Newfoundland and Labrador, being 10 miles, and the Gut of Canso, betwixt Cape Breton and the mainland, being only about half a mile in width at the narrowest part. The gulf is about 300 miles in length from N. to S., by 240 miles in breadth, and incloses numerous islands, the chief of which are,—Anticosti in the N., the Magdalen group in the centre, and Prince Edward's Island in the S. The estuary of the St Lawrence River debouches into the

Laybach
||
Lead.

gulf at the western extremity of Anticosti; although, properly speaking, this fiord is an inlet of the gulf as far up as the River Saguenay. Navigation is suspended here during winter and early spring, from the prevalence of ice, which is especially dangerous in the entrances to the gulf. Fogs, also, are very frequent during the prevalence of the E. winds in spring. In summer, however, the W. and S.W. winds render navigation comparatively safe. The fisheries, which are very valuable, are prosecuted with assiduity by the colonists as well as by United States companies. Herring, cod, and mackerel abound.

LAWRENCE, *St.* See CANADA.

LAYBACH (ancient *Æmona*), a fortified town of Austria, capital of Carniola, and of the former kingdom of Illyria, is situated on a navigable river of the same name, an affluent of the Save, 52 miles N.E. of Trieste; N. Lat. 46. 48., E. Long. 14. 30. The town and its suburbs stand on both sides of the stream, which is here crossed by several bridges. The castle, on a hill around which the largest part of the town is built, is now used as a prison. Among its public buildings are,—the cathedral, several churches and religious houses, Auersberg palace, a lyceum and gymnasium. A pillar stands in the market-place, raised in honour of the "Lady Conqueror of the Moon," *Mondbezwingerin*, a statue of whom is said to have rallied and led on the inhabitants when they were dispirited and had lost their general in one of the Turkish invasions. Laybach is the see of a bishop, and contains the law courts of the province. Its manufactures, which are unimportant, include porcelain, linens, and refined sugar; and it carries on an active trade in flax, grain, and wool. The Vienna, Bruck, and Trieste Railroad passes through the town. It is celebrated for a congress held here in 1821. Pop. (1851), 17,256.

LAZARITES, *THE*, an order of priests appointed by Vincent de Paule, and deriving their name from the Priory of St Lazarus, at Paris. Their mission was instituted in 1624, and in 1632 it was sanctioned by Urban VIII. The Lazarites suffered considerably as a body during the French Revolution, but after 1816 they were restored to their former position, and took an active part in the political movements which preceded 1830. In Poland they are numerous and influential, and their influence has been banefully exerted in retarding the progress of science. They have a footing in Spain and Austria; and in the East they have a mission in China.

LAZZARONI. See NAPLES.

LE, or LEE, the capital of Ladak, in Central Asia, is situated in a narrow sandy plain between the right bank of the Upper Indus, and a chain of mountains which rise on the N. to about 2000 feet; N. Lat. 34. 10., E. Long. 77. 38. It is 10,000 or 11,000 feet above the level of the sea, and is surrounded by a wall with towers, extending on either side to the summit of the neighbouring hills. The streets are narrow and irregular, and in some cases covered over to protect passengers from the sun's rays. The houses are from one to three storeys in height, built partly of stone and partly of unburnt brick. There are no chimneys, and the furniture is very rude and scanty. The only conspicuous building in the town is the rajah's palace, a square massive edifice, several storeys in height. Le is the seat of an active trade. Pop. about 4000.

LEAD, a simple metal of a bluish-white colour, of the specific gravity 11.44; its chemical equivalent is 103.57, and its symbol Pb, from *plumbum*. It is so soft as to be cut by the nail, to take impressions, and to leave a streak on paper. Its ductility and tenacity are low, but it admits of being rolled into sheets, and drawn into wire. Its fusing point is 620° F. It contracts considerably in passing from the fluid to the solid state, and hence is not well fitted for castings. It is an inferior conductor of heat and electricity. By being repeatedly heated and cooled, it becomes perma-

nently enlarged; whence the puckered appearance of the lead lining of sinks, &c., which are exposed to the action of hot and cold water. Lead.

There are four oxides of lead, only one of which, the *protoxide*, PbO, has basic properties.

Metallurgy of Lead.—The ore which supplies the greater portion of the lead produced in this country is *galena*, or the native sulphuret. The chief lead mines are in Derbyshire; but there are also mines at Allandale and other western parts of Northumberland; at Alston Moor, and other parts of Cumberland; in the western parts of Durham; in Swaledale, Arkendale, and other parts of Yorkshire; in Salop; in Cornwall; the Mendip Hills in Somersetshire; and in the Isle of Man. The Welsh mines are chiefly in Flint, Cardigan, and Montgomery shires; the Scotch in Dumfries, Lanark, and Argyll; and the Irish in Wicklow, Waterford, and Down.

Galena, when pure, consists of lead 86.55, and sulphur 13.45. It usually contains silver, and hence obtains the name of *argentiferous galena*. Galena crystallizes in the cubic system, and is deposited on a matrix of quartz, carbonate of lime, fluor-spar, or baryta. In the West of England the lead mines occur in clay-slate; in Derbyshire, and other northern districts, in limestone.

Preparatory to smelting, the ore is picked, broken, and washed, to separate earthy and stony matters; it is next roasted at a moderate heat, so as to allow of oxygen being absorbed, whereby about one-half of the ore is converted into sulphate of lead; this is mixed up with the unaltered portions, and the temperature is rapidly raised, so as to run the two together, when sulphurous acid gas escapes, and pure metallic lead remains behind. In this process the sulphur of the unaltered portion of the ore unites with the sulphur and oxygen of the other portion.

The furnace employed is represented in vertical section (fig. 1). Its sole is made up of the fused slags of former

Fig. 1.

operations, and the centre is hollowed, for the purpose of collecting the fused metal, which is drawn off by the tap-hole T, into a cast-iron pan on the outside. The arch of the furnace is depressed, so as to bring the flame of the fire into contact with the charge; this is let in by the hopper H, and is spread about and worked by means of iron paddles through the openings O, O, which also serve to supply air to the charge. At D is an opening for feeding the fire; C is the chimney; it is connected by means of flues, with condensing chambers, which prevent the poisonous lead fume from escaping into the surrounding district.

The charge varies from 12 cwt. in the north of England, to from 20 to 24 cwt. in Wales. It is spread evenly over the sole, and occasionally stirred for the purpose of bringing fresh surfaces to the air. After about two hours, some of the rich slags of former operations are thrown in. These quickly give up their metallic lead, and it is run out through the tap-hole. The heat is increased, and as the charge fuses, it is properly distributed over the sole. As the lead begins to collect at the lower part of the sole, quicklime

Lead. is thrown upon it, and, as the slags flow to the depression, they are pushed back to the fire-bridge. After from 3 to 3½ hours, the openings are closed, and the heat is urged for about three-quarters of an hour. After this the charge is again *rubbled*, to assist the flow of metallic lead into the hollow; the slags are pushed back, quicklime is added to set free a portion of the oxide of lead, and to reduce the liquidity of the slags, and allow of their being easily removed. The oxide reacts on any portion of the sulphuret not decomposed during the roasting; but it is now time to reduce the oxide, which is partly effected by the addition of powdered coal, and also by urging the heat for about 40 minutes, after which the furnace is tapped, and the slags, dried by a further addition of quicklime, are removed. From 7½ to 10 cwt. of coal are required for each ton of ore smelted, and the *shift* of the furnace, including the casting of the lead into pigs, occupies from 5½ to 7 hours. If the lead contain antimony or tin, which often happens with Spanish ores, it has to be refined by an operation called *improving*. The lead is melted in a shallow cast-iron pan set in the bed of a reverberatory furnace, and kept in that condition until the antimony and tin, which are more oxidizable than lead, have been entirely removed in the pellicle of oxide, which continually forms on the surface, and is frequently raked off. A sample of the lead is examined from time to time, and when it exhibits a peculiar flaky crystalline appearance on the surface, the metal is run off and cast into pigs.

Galena always contains a small proportion of sulphuret of silver, the proportion being subject to considerable variation; an ore which yields 120 oz. of silver to the ton, or 0·36 per cent., is very rich. Formerly the silver was extracted in a cupel furnace, called a *refinery*, in which the process of cupellation, similar to that described under ASSAYING, was conducted on a large scale. Of late years, however, a simpler and more economical process has been adopted, based on the fact noticed by Mr Pattinson of Newcastle, that if fused argentiferous lead be briskly agitated during its slow cooling, a portion of the metal solidifies in the form of crystalline grains, which subside. These crystals consist of lead nearly free from silver, the fusing point of the argentiferous alloy being lower than that of pure lead. All, therefore, that is necessary, is to separate the crystals thus formed, and in proportion as this is done, the liquid mass left behind becomes rich in silver. In Mr Pattinson's process, eight or nine cast-iron pots, each containing about 5 tons of fused metal, are set in a row, with a separate fire beneath each. A charge is introduced into the middle pot, and when it is fused the fire is put out, and the metal is briskly stirred during the cooling. As the crystals subside, they are removed by means of a large perforated iron ladle, and transferred to the next pot on the right hand. When about ¼ths of the metal have thus been removed, the argentiferous alloy is ladled out into the next pot on the left hand, and a fresh charge is added to the centre pot, which is treated as before. When the pots on the right and on the left hand have received a sufficient charge, either of very poor or of very rich alloy, they are submitted to a similar process, the concentrated argentiferous portion is again passed on to the next pot on the left, while the crystalline, or poorer portion, is transferred to the next pot on the right. At length the last pot on the left may contain lead with 300 oz. of silver to the ton, and it has not been found desirable to concentrate it beyond this point; the last pot on the right may contain lead with not more than ½ oz. of silver to the ton. This is cast into pigs for the market, and the lead is found to be greatly improved in quality by the process. Lead which contains from 3 to 4 oz. of silver to the ton, admits of being profitably worked for the sake of the silver, while by the old method of cupellation, ores containing less than 20 oz.

of silver per ton scarcely paid the expense of extracting the silver. The process of cupellation may, however, be profitably employed on the rich silver alloy contained in the extreme left hand pot. This process is based upon the fact, that lead by exposure to a current of air at a high temperature absorbs oxygen rapidly, and becomes converted into a fusible oxide, whilst the silver remains unaffected. The oxide of lead, or *litharge*, fuses at a high temperature, and flowing off from the convex surface of the molten metal, constantly presents fresh surfaces to the action of the blast.

In Great Britain, cupellation is conducted in a reverberatory furnace with a moveable hearth or *cupel*, consisting of an oval shallow basin, made of a mixture of bone-ash and a small quantity of wood ashes; the two being slightly moistened, are beaten into an iron ring, about 4 feet by 2 feet; this cupel is supported in the furnace by means of bricks; when dry, the fire is lighted, the heat gradually raised, and the lead placed in the cupel; when melted, a blast of air from a tuyère is made to play over its surface; litharge forms in large quantity, fuses, and flows off through a gutter into an iron pot beneath the furnace. Lead is added from time to time to supply the place of the oxidized portions, until about 5 tons have been reduced to 2 or 3 cwt. The molten mass is run out through a hole made in the bottom of the cupel; the hole is then closed with fresh bone-ash, and another charge introduced. When sufficient metal has thus been collected to produce from 8000 to 5000 oz. of silver, the process is repeated in order to remove the last portions of lead. This separate process is found desirable, since towards the end of the process the litharge carries much silver with it, which litharge is reduced, and the silver obtained from it as before. The litharge obtained from the first process is sold as such, or it is reduced in a small reverberatory furnace by means of powdered coal or anthracite. The porous cupels are also passed through the furnace, in order to obtain the metal absorbed by them. In the earlier stages of the process, the litharge forms on the surface of the melted metal as quickly as it flows off; but when nearly the whole of the lead has been oxidized, the film becomes thinner and thinner, and at length thin enough to exhibit the beautiful iridescent tints of Newton's rings. The last film suddenly breaks up, and reveals the brilliant surface of the metallic silver, known as the *fulguration* of the metal, and this indicates the completion of the process.

In the N. of England the galena is first roasted, and then reduced in a small square blast furnace or forge-hearth, known as the *Scotch furnace*. The rectangular cavity of masonry C (figs. 2, 3), is lined with cast-iron, and the sole-plate S is of the same material, furnished with an upright

Fig. 2.

Fig. 3.

ledge at its back and two sides. The sole-plate is brought

Lead.

forward to the front of the hearth, or a separate cast-iron plate is attached to it, called the *work-stone* W (fig. 2). This also has a ledge, except towards the sole. The whole plate is set with a slope, so that the hinder ledge is about $4\frac{1}{2}$ inches above the surface of the hearth. The reduced metal accumulates until it rises above the raised ledge, when it flows out by gutters *g* (fig. 3) in the work-stone, and is received into the melting-pot P. Above the hinder ledge of the sole is a block of cast-iron called the *back-stone*, and on this is the tuyère *t*: on this is another piece of iron called the *pipe-stone*, furnished with a cavity below for the passage of the tuyère. The back wall of the furnace is crowned by another piece of cast-iron, called the *back-stone*. The ledges of the two sides of the sole support bearers of cast-iron, above which, resting on fire-bricks, is another piece of cast-iron, called the *fore-stone*, while the space at each end of the fore-stone is closed by a cube of cast-iron, called a *key-stone*; two similar stones fill up the space between the fore-stone and the back part of the furnace. The front of the furnace is open for about 12 inches from the lower part of the front cross-piece or fore-stone, to the upper part of the work-stone, through which opening the workman operates. The fume is prevented from escaping into the smelting-house by means of a hood of masonry or brick-work.

The ore is first roasted on a long flat hearth, covered by a low arch, and heated by a fire at one end, the object being partly to oxidize and to get rid of sulphur. The roasting occupies from two and a half to three hours, on a charge of from 9 to 11 cwt., and the heat is managed so as not to fuse the galena; while the refuse of the ores, and other matters, are agglutinated so as not to be carried off by the blast. After a charge has been run out of the smelting furnace, a portion of imperfectly reduced ore remains behind; it is called *browse*, and is mixed with coke and clinkers, and used in the next charge. A quantity of peat, in blocks, is also built up in the furnace, near the front; this is ignited by means of a lighted peat, thrown in before the tuyère *t*, a small portion of coal is next added, and then some of the browse. The matters on the hearth are next raked out upon the work-stone; the refuse of the ore, or *gray slag*, which is more resplendent than the browse, is removed and thrown outside to the right, while the browse is returned to the furnace with a small portion of coal. A peat is put before the tuyère to prevent it from choking, and also to diffuse the blast. Quicklime is added, if necessary, to solidify the slag of the browse, or to render more fusible any silica, alumina, or iron, which may be present in the ore. The gray slag is treated in a slag-hearth at a stronger heat. The browse being returned to the furnace, some of the ore is strewed over it, and in about a quarter of an hour the materials are again raked upon the work-stone, the gray slag is removed, while a quantity of metallic lead passes off by the channels *g*, into the pan. Another peat is put before the nozzle of the blast, coal and quicklime are added, and the browse is returned to the furnace, with a fresh quantity of ore. After another interval of about a quarter of an hour, the slag is once more separated, and another quantity of metallic lead flows into the pan. This mode of working is continued about fifteen hours, during which from 20 to 40 cwt. of lead, and upwards, are produced. The lead is of excellent quality, since, on account of the low temperature employed, metals of high fusing points, with which the ore may be contaminated, remain behind, and only the lead and silver escape into the pan. The furnace in which the slags are reduced is in the form of a rectangular prism 26 inches in length, 22 in breadth, 33 in height. The bottom inclines slightly from the tuyère towards the front, the fire-hearth is formed of two stout plates of cast-iron, 26

inches by 12 inches, supported by bearers at the sides. A space of about 5 inches is left between these plates, or *stones*, as they are called, and the bottom of the furnace, and there is also a row of fire-bricks between. Preparatory to working the furnace, the bottom is covered with cinders, beaten together, and the pot which receives the lead is filled with them. Peats are next added to the furnace and ignited, then comes a layer of coke, and when the heat is sufficiently strong the slags are added. The space is kept filled with alternate layers of coke and slag, and as the slag melts, the lead contained in it filters through the bed of peat cinders, while the more viscid slag remains behind. The slag is run out by perforating the coke bed with a bent iron rod, and after passing over the surface of the pot which receives the lead, it escapes into a large iron cistern, sunk in the earth, containing cold water, which causes the slag to fly to pieces, thus fitting it for washing and other mechanical processes for separating any metal which may yet remain in it. The high temperature necessarily employed in the slag-hearth deteriorates the quality of the lead produced. This furnace is also employed for reducing certain ores which are not rich in metal, and also for some of the carbonates in which silver is an object rather than lead.

The neighbourhood of lead works is liable to contamination from the escape of lead fume. Professor George Wilson states that, in 1851, he had within five months to make a series of analyses with reference to the deaths of thirteen horses and several cows, which were supposed to have been poisoned by compounds of lead, transferred by the air or the water to the fields in which they were pastured. The grass of such fields was found to be impregnated with carbonate of lead; and in two cases the water drunk by the animals was found to be contaminated with the water used in washing the ore. Lead was found in several of the organs of the animals, especially the spleen, which, from its small size, spongy texture, and comparative freedom from fatty matter, admits of being rapidly and satisfactorily examined; and lead being found in this organ, it would not, in general, be necessary to seek for it in other organs.¹ At some works attempts are made to condense the fume, by making the flues of the furnaces communicate with chambers in which cold water showers down from the roof; at other works, the gases from the flues are drawn through cold water. At the Duke of Buccleuch's works at Wanloch, in Dumfriesshire, the condensing apparatus, constructed about 100 yards from the smelting furnaces, consists of a rectangular block of masonry about 30 feet high, divided by a partition into two chambers, the first of which, the *condensing chamber*, receives the fumes from the furnaces through a large pipe; while the second, called the *exhausting chamber*, communicates with a lofty chimney. The condensing chamber is formed into two distinct compartments, by means of a pair of vertical walls, placed 2 feet from each other so as to form a kind of flat pipe, open at the top, and running the whole width of the chamber, into which water falls in drops, produced by passing the water through a filter of pounded coal, situate in the upper part of the flat pipe. The condensing chamber is further divided into five compartments, each 6 feet high, by means of four horizontal floors, the last compartment corresponding to a bed of coals which forms a filter for the smoke. When the smoke enters the condensing chamber, it has to pass in zig-zags through the five compartments, and then through the bed of coal, on its way to the exhausting chamber. The opening which conducts the smoke from the exhausting chamber to the chimney is situate in its lower part, so that the smoke has to pass through the whole of the exhausting chamber where it

Lead.

¹ *Monthly Journal of Medical Sciences* for May 1852.

Lead. meets with an abundant shower of rain. This shower is regulated by a contrivance in the upper part of the chamber, where the top is covered with a large iron lid with twelve grooves about an inch wide. This lid is furnished with a slide, with openings of the same size, and moving upon it so as to open or close the grooves, while a current of water, being conducted from the upper part of the chamber, falls at intervals through the openings, and produces a copious shower in the chamber. "The atmospheric pressure acts on each movement of the slide with a force resembling that of a blast of an iron furnace, and produces an action sufficiently powerful to mix the impure vapours with the water, so that smoke at length passes into the atmosphere deprived of its injurious properties. The saturated water proceeding from these chambers is afterwards conducted into a reservoir, where it deposits the particles of lead salts that the fumes had carried off."¹ In the Great Exhibition, specimens of fume, thus recovered, were shown, containing 33 per cent. of pure lead, and about 4 oz. 17 dwts. 7 grs. of silver per ton. It is stated that the results of the above arrangement are most beneficial to the surrounding district. Formerly the noxious fumes poisoned the neighbourhood, burnt up the heather, destroyed the vegetation, and rendered it impossible for a beast to graze, or a bird to feed, near the spot. The heather now grows in luxuriance close to the works, sheep graze within a stone's throw of the chimney shaft, and game seek cover on all sides.

About 55,000 tons of lead are annually raised in England, from which about 150,000 oz. of silver are produced. In the year ending 31st Dec. 1855, the quantity of lead exported from the United Kingdom amounted to 22,353 tons, of the declared value of £512,426. In 1854, 19,605 tons, and in 1853, 16,242 tons, were exported.

In Germany, and some other parts of Europe, where poor ores of lead are treated, the sulphurets are reduced by means of granulated metallic iron; the iron combining with the sulphur of the lead forms a fusible sulphide of iron, and the lead is set free. This method is useful where the ores are largely mixed with silica, which, under the English method, would combine with oxide of lead, and form a fusible slag.

Metallic lead is used in the arts in the form of sheets for covering roofs and pipes for conveying water; also in the manufacture of shot, type-metal, solder, &c.

When lead is exposed to the action of air and pure water, it is partly corroded, and hence lead pipes and lead vessels for conveying or containing water for culinary purposes, may act as sources of poison. By such exposure the lead becomes converted at the surface into an oxide which the water dissolves; the solution absorbs carbonic acid, and a film of hydrated oxy-carbonate of lead is deposited in silky scales; a fresh portion of oxide is then formed and dissolved by the water; and so on. This action is greatly modified by the presence of different salts in the water, although the quantity may not exceed 3 or 4 grains to the gallon; the corrosive action being increased by the chlorides and nitrates, and diminished by the sulphates, phosphates, and carbonates, so much so, that oxide of lead is scarcely soluble in water containing these salts. Bicarbonate of lime exerts a remarkable preservative influence, and as it is a very common impurity in water, few spring waters exert much action on lead. In such cases a film of insoluble carbonate of lead is formed upon the surface, which serves as a protection to the metal. Rain water which pours into

cisterns from the roofs of houses, is usually sufficiently impure, especially in towns, to reduce its action on the metal. The hydrated oxy-carbonate of lead is the least soluble among the salts of lead; pure water not taking up more than about $\frac{1}{100}$ th of a grain per gallon. By exposure to the air, a solution of oxide of lead, by absorption of carbonic acid, forms silky crystals of the hydrated oxy-carbonate, and in a few hours, only a very minute portion of the metal will remain in solution; but water highly charged with carbonic acid may dissolve lead to a dangerous extent, from the solubility of carbonate of lead in excess of carbonic acid; but, by boiling, the gas is expelled, and the carbonate subsides. Traces of lead may generally be found in water that has been stored in leaden cisterns, so that slate ones are to be preferred. Lead is corroded in the presence of moisture by contact with sulphate of lime; hence, in using it for building purposes, the contact of stucco or plaster should be avoided.²

White Lead.—There is an enormous consumption of lead in the manufacture of white lead, which forms the basis of all ordinary oil paints, constituting at least $\frac{1}{10}$ th of their composition. There are various methods of manufacturing white lead, the two most important of which may be briefly noticed. In the Dutch method, as it is called, which was introduced into England about 1780, and is still carried on at Newcastle-upon-Tyne, and other places, a number of small glazed earthen pots, of the shape shown in fig 4, contain in the lower part a quantity of weak malt vinegar V, and above this is placed a spiral of thin sheet lead L; the pots are arranged in rows, with a plate of lead over each, and then in tiers to a height of 18 or 20 feet, and covered up with fermenting tan, partly new and partly spent, or with decomposing stable manure; the moderated warmth thus produced causes the vinegar to evaporate, and, under the united action of the air and the acid fumes, an oxide of lead is formed on

Fig. 4.

the surface of the metal, which oxide, combining with the acetic acid, forms a basic acetate of lead; the carbonic acid from the decomposing hot-bed converts this salt into carbonate of lead, whilst the neutral acetate again combines with a fresh portion of newly-formed oxide and forms the sub-acetate, which is again decomposed; in this way decompositions and recompositions take place in succession, the neutral acetate dissolving the oxide and forming the sub-acetate, while this is again decomposed under the influence of carbonic acid. In this process the quantity of vinegar required is very small, the function of the acid vapour being to act as a sort of carrier between the carbonic acid evolved from the hot-bed, and the oxide of lead formed under the influence of the acid vapour and the oxygen of the air. One part of pure acetic acid to 100 parts of lead, is sufficient for carrying on the process. The carbonate of lead slowly forms a compact layer on the surface of the coils, and it breaks off in flakes on unrolling them, forming the dead white colour which is so much in request, notwithstanding its poisonous properties.³ Before it is ready for the painter it is ground up with water into a thin paste, and is then reduced, by successive washings and subsidences, to an impalpable powder, which is collected in earthen pans, and dried at about 190°. When dry the powder gives no signs of crystalline structure, even under the microscope.

During the pulverization, particles of the powder escape

¹ Jury Report of the Exhibition of 1851, Class I.

² Professor Miller's *Elements of Chemistry*, part ii., 1856.

³ The innocuous oxide of zinc has been introduced as a white paint, in the place of white lead, but it has failed from the circumstance of its being partially transparent, so that it does not possess the covering properties, or *body*, of white lead. Moreover, the oxide of zinc will not combine with oil to form a plaster as oxide of lead does; hence it is a long time in drying.

Lease.

town and fashionable watering-place of England, county of Warwick, on the Leam, which is here crossed by two handsome stone bridges, about 2 miles E. of Warwick. In 1811 it had only 60 houses, and 543 inhabitants. It is now a favourite watering-place, and one of the handsomest and pleasantest towns in England. The surrounding country is highly picturesque, while Warwick Castle, Kenilworth, Stratford, &c., are at no great distance. The most elegant houses are mostly in the new town, on the N. side of the river. Among the finest of the public buildings are, the new pump-room and baths, the town-hall, the parish church, Trinity church, and the proprietary college, erected in 1847. The educational and benevolent institutions are numerous. Among the latter is the "Warneford Hospital," endowed by Dr Warneford, for affording to the poor baths and medical advice gratis. The Jephson, Ranelagh, and Priory gardens form delightful promenades. The first is of considerable extent, and has a statue of the founder, Dr Jephson. There are no manufactures of importance in the town, the inhabitants being chiefly dependent on the visitors that resort thither. The ordinary season is from May to October. The springs of Leamington are saline, sulphureous, and chalybeate. Pop. (1861) 15,692.

LEANDER. See HERO.

LEARCHUS, a celebrated Greek sculptor of Rhegium, in the S. of Italy, who seems to have flourished at a very early period, before 620 B.C. He made a statue of Jupiter in bronze, which was seen at Sparta, and which was regarded as the most ancient work of its kind. It was not of one piece, but was made of pieces worked separately, and fixed to one another by means of nails and large hooks, so that the parts could not be separated. It is this species of work which Quatremère de Quincy has perfectly explained, under the name of *Sphurelaton*, in his *Jupiter Olympien*. (Pausanias, iii. 17. See Winckelmann, *Op.* vi. 1, 7.)

LEASE, a word akin to the verb to let (French, *laisser*; German, *lassen*), may be defined as a conveyance by contract from the lessor of lands, tenements, &c., for a given term of years or at will, in consideration of rent paid, or other service rendered by the lessee. As distinct from an assignment, the lessor, in granting a lease, does not part with his interest in the subjects leased, and hence there is no valid lease where there is no reversion; and by virtue of this reversion the lessor is invested with power to distrain in failure of payment or in case of any other breach of fealty. Whatever words be used in granting a contract of lease (the usual form being "demise, grant, and to farm let"), the duties and rights of both parties are secured when there is sufficient evidence of an intent on the part of a proprietor of yielding, and on the part of the lessee of holding, possession for a determinate time. Originally, when no writing was necessary, a valid lease was not completed without actual entry; but now, although a deed is necessary only in a few exceptional cases, arising from some peculiarity in the nature of the property to be leased, leases, like other covenants, are generally made by deeds. The conditions on which a lease is granted may embrace anything that is lawful; and there is no authority which can interfere with the granting of leases on any term by parties who have the complete ownership of the property. In cases where ownership only amounts to a divided interest in the subjects, leases are granted under particular powers according to certain statutes; but certain classes who have only a temporary interest in the property, and hold it, for example, only during a precarious tenure of office, are (as the holders of benefices by 18th Elizabeth, chap. 20) restrained from executing deeds of this nature, intended to be valid beyond the period of their proprietary. An act passed in 1845 (8th and 9th Vict., c. 124) has for its object the simplification of the terms used in granting leases. Without rendering invalid the forms previously in use, it

Lease.

gives schedules of abbreviated expressions which are considered to be equally legal with the older and more cumbersome forms, and when taxed are, *ceteris paribus*, to be regarded as involving equal merit by the taxing officer. This act, however, does not extend beyond England.

In Scotland the first statute in favour of tenants was that of 1449, c. 17, which secured them against purchasers of the lands, until the expiry of their lease, provided they paid their rent to the new proprietors. Before that date a lease was disregarded in a competition with a subsequent proprietor, whose titles were completed by charter and sasine. To bring the lease under the protection of the statute, it must be granted by a legally qualified party,—it must be in writing, and definite as to rent, and term of endurance. The tenant must also be in actual occupancy under it. Though these conditions are required to render the lease available against third parties, who subsequently become proprietors, they are not required for the purpose of protecting the tenant against the granter of the lease and his heirs. A perpetual lease, or one with a nominal rent, or which directs the rent to be disposed of otherwise than in payment to the landlord, or entitles the tenant to demand a renewal for ever, is good, not only against the landlord by whom it was granted, but against his heirs, seeing that his heirs cannot be in a better position than the party whom they claim to represent. To protect the tenant against strangers coming by purchase, or by the act of the law as creditors, into what is called the feudal right to the lands, it is necessary that the granter of the lease have his own title, as proprietor, made up by charter and sasine, or at least that that be done before the ownership of the lands passes out of his hands. If the granter be a pupil, a lease cannot last longer than the office of his tutor; but minors, that is boys above fourteen, and girls above twelve years of age, may, with consent of their curators, grant leases to endure after their majority, provided the terms be just and equitable. If the terms be injurious to the minor, the lease may be set aside on that ground, if challenged by an action at law raised within four years after the minor attains majority. A lease granted by an heir, who, in virtue of his apparenancy, has been three years in possession, though he may not have made up his title, will be good against a subsequent heir, but not against either an adjudging creditor, or a subsequent proprietor. The owner of an estate who has granted an heritable bond over it, may afterwards grant a valid lease, but not after certain steps have been adopted to recover the debt, commencing by what is called adjudication; nor after the use of inhibition, which is a preventive measure, unless the lease be according to the course of ordinary administration. If the estate of a proprietor be sequestrated for debt, he can no longer grant a lease; neither is one granted on deathbed available to the prejudice of the heir-at-law. A liferent proprietor may grant a lease to terminate at his death. Heirs of entail in possession can only grant such leases as the deeds of entail permit.

As it is presumed, unless otherwise specially provided by the lease, that the tenant is merely entitled to the annual produce of the lands, or occupancy of the houses and the like, it follows, that unless otherwise provided, mines and minerals, trees, the right of hunting, and the landlord's right over the crop of each year in security of the rent of the year of which it is the crop, are reserved to the landlord. The security over household furniture, cattle, or stocking, lasts for three months after the last term of payment of the year's rent. In the use of reserved rights, the landlord must compensate the tenant for any damage which, in the exercise of these rights, he may occasion.

The destination of a lease is matter of arrangement, otherwise it goes to the heir-at-law of the tenant on his death. A tenant's creditors, and even his assignees, as well as his right of subsetting, may be excluded. All questions

Lease. of this kind should be well considered and provided for when the lease is being entered into.

The tenant is bound to stock, manure, and labour the farm according to the rules of good husbandry; and he has right to the annual fruits, and to the occupation of the subject. If the subject be destroyed, as, for example, if a house or mill be burnt down or become ruinous, or a mine becomes unexpectedly exhausted, no rent is exigible. Even where, from some extraordinary calamity, land has become sterile, or, from remarkable inclemency of the weather, the crop is lost, so that the tenant cannot recover the value of the seed, rent cannot be exacted. Where such occurrences as these do not happen, the conditions of the lease must be strictly observed on both sides. The landlord and his heirs must protect the tenant in his possession during the currency of the lease; and the tenant must pay his rent and perform all the other obligations which he has undertaken. It is the duty of the landlord to uphold the subject leased, unless otherwise provided, and the tenant is responsible for such damage as he may occasion, ordinary tear and wear excepted.

We have said that a Scotch lease must be in writing. A verbal lease is in no case binding against any party for more than one year, and a written lease, silent as to the period of its duration, is regarded as being for one year only, or for the shortest period beyond a year that can be construed from its terms. In some cases where money has been expended to a large amount on the faith of a verbal lease, damages may be given; and where it appears that the party challenging a verbal lease, has done some act, plainly in recognition of a succeeding year, the lease will be sustained till the expiry of such succeeding year; but that only in questions with the grantor and his heirs, and not in questions with succeeding proprietors. As a verbal lease may be resiled from after a year, it is not competent to establish a longer duration by a reference to oath. On the other hand, though writing is required, it is not necessary that it should be a formal, or, as the law of Scotland calls it, a probative writing, provided it have been followed by possession of the subject on the part of the tenant. Accordingly, a written obligation to grant a formal lease, followed by possession, will save the rights of the tenant, not only against the grantor and his heirs, but even against third parties who have subsequently become proprietors, provided it expresses the requisites of the Act 1449—namely, a fixed rent, and a definite period of endurance. It is not necessary that the fixed rent be in money; a grain rent, or even service is sufficient; but if the rent be nominal (although no criterion for determining what is elusory, has yet been authoritatively settled), or if the rent is to be retained till a debt due by the landlord is extinguished, the lease will be voidable at the instance of a subsequent proprietor. In the same way, if the term of endurance, though determinate, be unusually long,—such as, while water runs down, or grass grows up,—or if it be renewable for ever, or even for a period unknown in ordinary practice, the lease will be voidable at the instance of a subsequent proprietor, as being substantially destructive of the right of property, though it may be available against the grantor and his heirs. Of course it is otherwise if the purchaser, at acquiring the property, was taken bound to recognise the lease, or, if he afterwards voluntarily homologated it. It is to be regretted that no judgment has yet been given in Scotland fixing the utmost length of lease that shall be available against subsequent purchasers. All, we believe, that can be safely said on this subject at present is, that a lease for twice nineteen years, is usually regarded as suitable where improvements are contemplated; and that in coal or mineral, and building leases, owing to the great expenses involved, an enlarged period, in order that the tenant may be indemnified, is usual. Liferent leases seem to be unobjectionable. Sometimes a lease declares that

part of the rent shall be expended in necessary improvements on the subject leased, and such a lease will be binding against a purchaser, provided the improvements be executed subsequent to the date of his purchase, as they enhance the value of the subject: but if they were executed prior to the date of his purchase, they will not form a claim of abatement from the rent, because it is to be presumed that the purchaser paid an increased price for the improved subject. In this last case the tenant's claim for indemnity will lie only against the seller or his heirs. If improvements to be executed after the date of the purchase, are of an extraordinary character, such as the building of a new house, the purchaser may prevent their being executed, leaving to the tenant his claim of damages against the seller.

A power of assigning a lease, or sub-letting the subject, is not implied, unless the lease be for more than nineteen years, or is given to the tenant in liferent, or unless the subject leased be an urban tenement. An assignment and a sub-lease require for their completion to be followed by possession. The shortest lease, however, may be attached by the tenant's creditors, by what is called adjudication, unless it contain a clause expressly excluding assignees and sub-tenants; and then neither voluntary nor judicial assignees can be received.

When a lease has reached its natural termination, unless it be a liferent lease, it is still held to exist from year to year on its original terms, by what, in Scotland, is called tacit relocation, until either the landlord shall intimate to the tenant, or the tenant shall intimate to the landlord, his intention to have it terminated; and such intimation must be made forty days before the term of Whitsunday of the year in which it is meant to bring the lease to a close. This intimation is called a warning. It may be given many ways. One mode, proceeding on a precept from the landlord, is regulated by the Scotch statute 1555, c. 39. Another mode is regulated by an Act of Sederunt of the Court of Session, dated 14th December 1756. By a recent statute regulating sheriff-court procedure, the length of the warning required by the Act of Sederunt has got six days added to it. Even where there is a regular lease, in which there is generally a clause binding the tenant to remove at its expiry without warning, he is entitled to rely on the lease being continued by tacit relocation, till he receive a regular warning. On such a lease it is competent, prior to the forty days, to give a charge in virtue of letters of horning to remove. A lease may be brought to a close before its natural term, by the tenant's desertion, or failure to pay his rent. In such a case the landlord should apply for judicial authority to let the lands for the unexpired portion of the lease. It is also competent to proceed by a summons before the sheriff, concluding to have the tenant ordained, within a certain time, to stock and plenish the farm, and labour and manure it in terms of his lease; or if the lease be silent as to the mode, according to the rule of good husbandry; and failing his doing so, that he should be removed, and the landlord found entitled to resume possession. The tenant may be removed by a like form of process, if he have subset the farm contrary to the provisions of the lease, or if he have suffered two years' rent to remain unpaid. This last ground of irritancy is provided for by the Act of Sederunt 1756; and unless the arrears be paid before judgment is pronounced, the lease is at an end. Even where a tenant falls into one year's arrear of rent, or deserts his farm at the usual time of labouring it, the landlord may, by the same Act of Sederunt, sue the tenant to find security for the arrears, and the rent of the five following years, within a certain time, to be limited by the sheriff, under pain of compulsory removal. Of course a written lease may be terminated at any time by a written renunciation executed by either party, and accepted in writing by the other.

Lease.

Leather. In urban tenements a warning to remove is sufficient if it be proved to have been given verbally, or by a peculiar form called chalking the door by a burgh officer.

The rights of the feudal superior of the subjects remain always unaffected by any transaction between landlord and tenant.

Leases in general require an *ad valorem* stamp. Leases in consideration of a premium, without any yearly rent, or with a yearly rent under L.20, are charged the same amount, with the exception of leases and tacks for lives, not exceeding three; and leases for a term absolute, not exceeding 21 years, granted by ecclesiastical corporations, aggregate or sole, when the duties on such leases would, under 13th and 14th Vict., c. 97, amount to 35s. or upwards.

STAMP DUTY.	Term not exceeding 30 years.	Above 30 and not above 100.		Exceeding 100 years.
		L. s. d.	L. s. d.	
Rent not exceeding.....L.5	0 0 6	0 3 0	0 6 0	
Above L.5, and not above 10	0 1 0	0 6 0	0 12 0	
... 10, ...	15 0 1 6	0 9 0	0 18 0	
... 15, ...	20 0 2 0	0 12 0	1 4 0	
... 20, ...	25 0 2 6	0 15 0	1 10 0	
... 25, ...	50 0 5 0	1 10 0	3 0 0	
... 50, ...	75 0 7 6	2 5 0	4 10 0	
... 75, ...	100 0 10 0	3 0 0	6 0 0	
Exceeding L.100, then for every L.50, and for any fractional part of L.50...	0 5 0	1 10 0	3 0 0	

In the case of a lease under thirty years, if the rent be under L.20, and a fine, premium, or grassum be paid, then the duty is to be the same as on a sale; and if the rent be above L.20, both the lease-duty and sale-duty are exigible. In the case of a lease, to which the second and third columns apply, where there is a fine, premium, or grassum, and whatever the amount of rent, both the lease and sale-duty are exigible. See 13th and 14th Vict., c. 97, and 17th and 18th Vict., c. 83.

LEATHER. The skins of various animals, in their fresh state, are flexible, tough, and elastic, and appear to be admirably adapted to the purposes of clothing. But in drying they become hard and horny, and, on exposure to moisture, putrid. The art of restoring the supple qualities to skins, and rendering them durable, appears to have been discovered at an early period of man's history; and the word *leather*, from the Saxon *lih*, *lithe*, or *lither*, indicates the quality of suppleness.

Leather is formed by the chemical union of the *dermis*, *corium*, *cutis*, or true skin of an animal, with an astringent vegetable principle, known as *tannin* or *tannic acid*. The word *tan*, from the French *tanner*, to tan, appears to be derived from the low Latin *tanare*. Leather may, however, be prepared by impregnating the skin with alum, oil, or grease.

In the animal hide or skin, the outer part, which is covered with hair or wool, is called the *epidermis* or *cuticle*, below which is the *reticulated tissue*, and then, in contact with the flesh, is the *dermis*, or true skin, which is the only part which admits of being tanned. It varies in thickness in different parts; the mane, the back, and the rump, being thicker than the belly. The skin is converted into *gelatine*, or *glue*, by the action of boiling water.

Varieties of Leather.—The leather tanned in England is generally divided into three kinds, namely, *hides*, *kips*, and *skins*, and these yield different varieties of leather, such as *butts* and *backs*, which are made of the stoutest and heaviest ox-hides. Fig. 1 will show how the butt is formed by cutting off the cheeks, the shoulder, and a strip of the belly on each side, the skin of the head having been previously removed for the use of the glue-maker. For backs, the cheeks and belly are cut off, but the shoulder remains. Hides are similar to butts with the bellies on, and are made out of cow-

hides, or the lighter ox-hides. When hides are tanned whole for sole leather, they are called *crop hides*. Skins produce the lighter varieties of leather. Large quantities of hides, dry or salted, are imported into the United Kingdom from South America and different parts of Europe, from the Cape of Good Hope, Morocco, &c. Calf skins are imported from the Baltic, and the calves being killed younger than in this country, the leather prepared from them is used for bookbinding, gloves, and ladies' shoes.

Fig. 1.

The stoutest leather is made from butts or backs. Buff leather was formerly made from the hide of the buffalo, but it is now furnished by cow-hide, and is used chiefly for soldiers' belts. Bull-hide is thicker than cow-hide, while that of the bullock is intermediate. Calf-skin supplies the great demand for the upper part of boots and shoes. Sheepskins form a thin cheap leather; lamb-skins are used for gloves; goat and kid skins form a light leather of fine quality; deer and antelope are usually *shamoyed*, or dressed in oil; horse-hide is prepared for harness-work, &c., and this, with seal-skin, is used for making enamelled leather; dog-skin makes a thin tough leather, but most of the gloves sold as dog-skin are made of lamb-skin. Hog-skin makes a thin porous leather, and is used for covering the seats of saddles. There is a large import trade in skins. The great demand for leather for the best gloves is supplied by lamb-skins from Italy, Spain, the south of France, and other parts, where, in consequence of the lamb being killed earlier than with us, the skin is small, fine, and thin, and is used instead of kid; but it is neither so strong nor so glossy. The skins of lambs that die soon after their birth are sometimes dressed with the wool, and are used for lining gloves and shoes. The best kid-skins are from the south of France: they are also imported from Germany, Switzerland, Italy, and Ireland. It is said that as soon as the kid begins to feed on herbage, the skin suffers in fineness and delicacy, and is no longer suitable for the best gloves. The best morocco leather is made from Swiss goat-skins, another kind is from Mogador and East Indian goat-skins, which are often made into black morocco, known as "Black Spanish leather," from the circumstance of our first supplies having been obtained from Spain. The leather from the Cape sheep-skin is nearly equal to morocco. Hippopotamus hides are imported from South Africa, and when tanned with oak-bark, they make an extremely thick and compact leather.

Tanning Materials.—The vegetable substances used in tanning have of late years become almost as numerous as the varieties of hides and skins on which they are employed. The active vegetable principle tannin varies somewhat according to the source from which it is derived; but it is always marked by an astringent taste, a bluish-black, or dark green precipitate, in aqueous solutions, by admixture with a solution of one of the salts of peroxide of iron; while, with a solution of gelatine, it gives a dirty white or brown precipitate. A cold aqueous solution of tannin, mixed in certain proportions with one of gelatine in the form of glue, size, or isinglass, forms a substance which is known as *tanno-gelatine*, which may be formed by the application of heat into a viscid elastic mass, resembling India-rubber. By the action of ether, containing a little water, on galls, pure tannin may be procured. The ethereal solution separates by repose into two layers, the lower one, which is of an amber colour, being a solution of tannin in water; while the upper layer contains gallic acid, mixed with other substances. On gently evaporating the aqueous solution,

Leather. nearly pure tannin is procured, to the extent of from 35 to 40 per cent., from galls. Obtained in this way, it is a shining, porous, uncrystallizable mass: it is soluble in water, and then exerts the properties of an acid. By exposure to air it absorbs oxygen, and gives off carbonic acid; two new products, gallic acid and ellagic acid, being formed at the expense of the tannin, the latter being insoluble. Tannin may be precipitated from its solutions by sulphuric and some other acids: by boiling the precipitate with sulphuric acid for a few minutes in a dilute solution of the same acid, gallic acid is formed, and crystallizes in cooling. Gallic acid exists in gall-nuts, sumach, valleronea, tea, and other substances, and probably arises from the decomposition of tannin. It does not combine with gelatine, and is, therefore, useless in tanning. Some tanners, however, imagine the gallic acid of the waste liquor to be useful in swelling or raising the hides, preparatory to removing them to a stronger liquor. It is important to the tanner to understand the circumstances under which tannin is converted into gallic acid: they are numerous and somewhat complicated, and their investigation belongs to the scientific chemist, to whom the manufacturer already owes so many obligations.

During a long period the principal tanning material in this country has been oak-bark. That which is stripped in the spring is the most esteemed, for it then contains a larger quantity of tannin than that stripped in autumn, and this more than the bark stripped in winter. The best bark is obtained in a warm spring, from coppice trees about 12 years of age. Oak-bark contains from 5.6 to 6.0 of tannin, which is contained in the inner white layers next the alburnum, as in the case of other astringent barks. The tannin of bark is probably not identical with that of galls, as it does not yield pyro-gallic acid, when subjected to destructive distillation. From 4 to 6 lb. of oak-bark are required for every pound of leather. A load of oak-bark, consisting of 45 cwt., delivered in London, varies from L.15 to L.16, 10s. After the stripping, the bark is stacked to dry. Should the season be rainy a portion of the tannin may be washed out, and the bark be thus deteriorated. There is no doubt that the peculiar excellence of the sole leather of England is due in great measure to the superior oak-bark which we possess. Oak-bark imparts firmness and solidity to leather, while other sorts give softness; thus the peculiar softness of French curried leather is referred to the bark of the evergreen oak, with which the better kinds are tanned, while the other tanning materials next to be named give each its peculiar quality with respect to colour, scent, toughness, or the power of resisting moisture and decay.

The other tanning materials, used chiefly for fancy leathers, are as follows:—Sumach, consisting of the young branches and powder of the leaves of *Rhus Cotinus*, *Venus sumach*, or the wild olive, and *Rhus Coriaria*. Sumach varies in its amount of tannin from 16.4 per cent. in Malaga and Sicilian specimens, to 10 and 5 in Virginia and Carolina sumach. The solution is liable to fermentation. *Divi*, or *divi-divi*, is the pod of a South American shrub, *Cesalpinia Coriaria*. The pod is dark-brown, about 3 inches long, and curled up as if by heat. It is rich in tannin, the whole of which is found in the rind below the epidermis. Valleronea, consisting of the acorn cups of *Quercus Agilops*, or prickly-cupped oak, growing in the Morea. A smaller kind, called *cornata*, containing a larger proportion of tannin, is for the most part used by the silk-dyers. About 2 lb. of valleronea are required for making 1 lb. of leather. Valleronea and oak-bark may be mixed together with good effect. *Catechu*, *cutch*, *Terra japonica*, or *terra*, are the inspissated aqueous extracts of the bark, wood, and leaves of the *Acacia Catechu*, and *Uncaria gambier*. The two varieties are known in commerce as catechu, or gambier, and cutch; that from Bombay is richer in tannin than that from Bengal. *Myrobalan* is a name given to the fruit of several East India trees; the

husk, being the portion valuable to the tanner, is separated by bruising the nut which it incloses. *Mimosa* or *Wattle-bark* is furnished by different species of *Mimosa* growing in Australia and New Zealand. *Cork-tree bark* is the inner bark of the cork oak, the outer or dead bark being the well-known substance, cork. It is obtained from Corsica, Spain, and a few other countries, and contains twice as much tannin as average oak-bark. *Larch-bark* is sometimes used for tanning sheep-skins, and *Willow-bark* for kid and lamb skins. The last named bark is used in making Russia leather, but its peculiar odour is given by means of the oil of birch-tree bark.

In addition to the tannin contained in the above substances, there are mucilaginous, colouring, and other matters which have an influence on the kind of leather produced. The tannin itself may also vary in different materials; thus, catechu and divi give a more porous leather than oak-bark or valleronea, while larch-bark gives a very inferior leather to that prepared from oak-bark. The colouring matter in some excellent tanning materials prevents their use, since it is the custom to sell both upper and sole leathers of a yellowish-fawn colour, and anything which interfered with the production of this tint would be objected to; thus, catechu and cutch would be among the cheapest of tanning materials, were it not that they impart to the leather a reddish-brown colour, which would in no way interfere with the dressing or currying.

The tanner frequently judges of the strength of his infusions of bark, technically called *ooze*, by means of a kind of hydrometer called a *barkometer*. It is graduated to the standard of pure water, and when placed in a specimen of *ooze*, the strength of the latter is judged of by the position of the stem above or below the water-mark. But as a bark or other tanning material may contain several soluble substances besides tannin, the barkometer obviously cannot be relied on.

Some tanners judge of the strength of *ooze* by the taste, the amount of astringency determining the strength. The usual test for tannin is a solution of glue or isinglass, which being mixed with a known weight of a solution of tanning material, a precipitate of tanno-gelatine is produced which is filtered, dried, and weighed: the proportion of tannin is thus ascertained. As, however, some kinds of tannin produce larger precipitates of gelatine than other kinds, and as the composition of tanno-gelatine varies with the strength both of the solution of gelatine and of tannin, this method is not reliable. Sulphate of quinine is said to afford a better test; a solution thereof, acidulated with a few drops of sulphuric acid, will, it is said, precipitate tannin completely from the solution. A good method of testing the value of tanning material is to digest a piece of dry prepared hide or skin in a known quantity of the infusion, until the whole of the tannin and other matters be separated. The skin is then taken out, slightly washed, dried, and weighed, when the increase of weight is supposed to be the weight of tannin and of the other matters required.

Tanning of Thick Leather.—The first operation to which the hides and skins are subjected is *depilation*, which removes not only the hair, but also the scarf-skin. This is effected variously in different countries. In England the most common plan is to throw the hide or skin into a strong watery ley of slaked lime, with lime in excess. Here, in a few days, more or less according to the proportion of lime present, the hair is easily detached, the hair-sheath having been dissolved; the scarf-skin with the hair are then scraped off upon a sloping rest, with a species of knife with two handles. The lime has also combined with the fat of the hide to form a calcareous soap, to dissolve which, and the excess of lime, it is well washed, sometimes in a running stream. The hide is fleshed, or deprived of the loose or extraneous flesh or cellular tissue; and if butts are to be made, the head, shoulder, and bellies are cut off, as

Leather.

Leather. already noticed. The central part, or butt, weighs about two-thirds of the whole leather. The hair was formerly taken off by making a sour liquor from fermented vegetable matter, in which the hide lay for several days; they were also smoked in a damp state for the same purpose; but both those methods are now abandoned. They are still sometimes sweated, that is, they are laid in heaps, and kept wet and warm; but in America the sweating is performed cold; the hides are hung up wet in a damp underground cellar, and are kept moist for ten days or a fortnight, a plan which is still adopted in this country for skins. In either of the three last processes, incipient putrefaction takes place sooner or later, when the hair and scarf-skin are easily removed; but the fatty matter remains, and in some cases prevents the hide from taking the tan. The tanning either follows at once, or is preceded by what is called *abating* or *grainering*. For this process, a quantity of pigeon's dung is dissolved in water. In this mixture the hides are steeped for a week or ten days, with occasional removals and striking. The theory of this process is obscure; but it has been explained on the supposition that the uric acid of the dung removes the excess of lime, and that the ammonia generated by the putrefaction of the mixture tends to form an ammoniacal soap with any remaining fat of the hide; but as the gelatine of the hide exists in two states,—one, the principal, hard, or fibrous portion, and the other (which is more soluble) contained between the fibres, and more affected by agents and putrefaction—this softer portion is removed by grainering, and the leather, when tanned, is light and porous, and more readily permeable to water.

Some tanners are anxious that their leather should look thick when completed. To "raise" the hide, they use a solution of sulphuric acid, containing $\frac{1}{10}$ th part of acid; in this the hides remain ten or twelve hours, when they are found to be thickened, or to have substance; but as nothing is added to the gelatine by the process, it is only the appearance which is altered, and no difference of thickness is found in the leather after it has been under the shoemaker's hammer.

The hide or skin thus prepared is ready for tanning. It was formerly the practice in England, as it now is on the Continent, to tan by the process of *stratification*, for which purpose a bed of bark is made upon the bottom of the pit; upon this is laid the hide, then bark, then a hide, and so on, until the pit is full; water is sometimes pumped in, and the pit left for some months; it is then emptied, and the same hides returned with fresh bark and water for a few months longer; this is repeated again and again, until the tanning is completed; the time varying from one to four years for heavy leather.

About the end of the eighteenth century, Seguin professed to give a theory of tanning. He showed that astringent solutions contained gallic acid, which precipitated sulphate of iron black, but did not precipitate gelatine; whereas the tannin present threw down gelatine as well as sulphate of iron; and from this he deduced that leather was a compound of gelatine and tannin. Upon this he founded a new process. He recommended that the hides should be subjected to the action of solutions of tannin, made by pumping water successively upon the vegetable used, contained in *latches* or *spenders*, until it arrived at as great a degree of strength as the series of spenders permitted. In this way he was continually throwing away some bark as expended, and replacing it with fresh, which was next to be the strongest tap.

This is the plan generally followed in England; but in practice it is varied, some using ground bark only, others *Terra japonica*, vallonea, or divi-divi, or mixtures of two or more; some using steam to facilitate the solution, others steaming only the backward latches; and some using only cold water. In some yards clean water only is used to extract the soluble matter, while in others the ooze, exhausted as much as it can be by the hides, is made to per-

form the office instead of water. Every tanner has also his own particular strength of liquor to work at, the strongest being about sixty degrees, while others do not go beyond ten degrees. It is these variations which cause so great a variety among the samples of leather in the market.

This improvement of Seguin was of importance in shortening the period of tanning to about half of that previously occupied. The principal difficulty experienced in its use occurs in the estimation of the real quantity of tanning material actually in solution. He proposed the use of a solution of gelatine, isinglass, or glue, which was to be dropped into the fluid as a test of the presence of the tannin. In the hands of an experienced chemist this is a tolerable means of arriving at the quantity; but it proved too difficult for the tanner of the day. He therefore judges by the astringent taste of the solution, and its darkness of colour; or depends upon its strength from a certain weight of bark, &c., which may have been used. The use of the barkometer has been already referred to.

In trying the quantity of tannin by Seguin's process, that is, by precipitating it with the solution of gelatine, 480 grains of the bark in coarse powder should be acted on by half a pint of boiling water. The mixture should be frequently stirred, and suffered to stand twenty-four hours; the fluid should then be strained through a linen cloth, and mixed with an equal quantity of solution of gelatine, made by dissolving glue, jelly, or isinglass, in hot water, in the proportion of a dram of glue or isinglass, or six table-spoonfuls of jelly, to a pint of water. The precipitate should be collected by passing the mixture of the solution and infusion through folds of blotting-paper, and the paper exposed to the air till its contents are quite dry. Every 100 grains of precipitate contains 40 grains of tannin nearly.

When the hide or butt has been brought from the beam-yard, it is introduced into a poor and milky liquor, in which it is *handled* for four or five days; that is, it is lifted by hooks from the pit, laid with other hides in a heap on the side, where it is allowed to drain, and is then returned into the pit. The lime is intended to be taken out here by the gallic and acetic acids of the poor ooze, as it is found in practice that the presence of lime tends to darken the colour of the future leather, an effect produced by all alkalies and alkaline earths. The hide is next successively handled into and out of all the handlers, increasing in strength; and in this way at length, having after some months got to the strongest handler, it is found to be stained through, though not tanned, when it is removed to the pits which contain still stronger liquors; these it successively passes through, being handled at longer intervals. Upon arriving at the end of this series, the hides are laid away in a pit called a *layer*, where they are interstratified with powdered bark or vallonea; the pit is then filled up with very strong ooze. When the process is deemed complete, each hide, on being taken out, will be found to be converted into leather; and a portion of its gelatine which has been dissolved from its interior is, by combination with a portion of tannin from the strong solution, deposited upon its surfaces, where it is found in the form of a yellow deposit, technically known as *bloom*, or *pitching*, which disguises the under colour of the leather, just as if it were covered with yellow paint. This, prejudice says, must be on its surface, or it is not saleable; but it is so much quality and weight lost to the consumer, as he pays for it on the outside of his leather, to be scraped off by the shoemaker in the operation of buffing; and the leather is so much the worse, as, if it had remained incorporated with the leather, this would not have been so porous, or so permeable to water. The health of the wearer of the shoe is perhaps sacrificed by wet feet, occasioned by the desire of his shoemaker to see a yellow paste on his leather, which in work he scrapes off with a piece of glass.

Leather.

Leather.

The theory of the formation of the bloom is this. As soon as ooze has penetrated into a hide, it loses its tanning material, but by capillary attraction is detained; this exhausted ooze acts by maceration on the finer and more soluble interstitial gelatine, and dissolves it. In handling, about one-twelfth of this flows out; the remaining eleven-twelfths accompany the hide into the next stronger solution, of which only one-twelfth is absorbed directly, and a small portion is slowly exchanged by endosmosis and exosmosis. The small portion of strong solution which passes into the pores of the hide contributes to tan the hard fibrous portions not dissolved; and the small portion of weak solution passing out of the hide by exosmosis, gives up its dissolved gelatine to the tan of the stronger solution outside, to form tannate of gelatine, which partly adheres to the surface as bloom, and partly falls to the bottom of the pit as pitching. It is to be hoped that such an exposition will tend to lead to the adoption of some system of tanning in which the exhausted ooze may be so quickly removed by pressure as not to allow it to dissolve the finer and better portions of the skin. Some years since, Mr Spilsbury endeavoured to introduce a new principle in tanning, by which some part of this action should be prevented, by bringing strong ooze at once into contact with the inside of the hide. He obtained a patent for a plan of tanning by infiltration. He fastened two hides in clamps, so that the frame represented four sides of a box, and the two hides two sides. By filling this box with strong tanning ooze, and forcing it through the pores of the hides by the pressure of a column of the fluid, he expected to tan them promptly and well; but he was not aware that a large excess of tannin dissolves gelatine, and thus tannate of gelatine was found on the outside of his box in long masses of slime, while the leather had lost as much in weight, was porous, and was tanned very much more in the thin than the thicker parts, as the fluid always passed through the easiest channel. Many other inconveniences attending the process caused it to be abandoned; but the erroneous principle upon which it was founded not having been made public, three other patentees followed in the same track. Mr Drake of Bedminster sewed hides together, so as to form a bag, which he placed inside a hollow frame-work of wood to support the bag, and then filled it with ooze. Mr William Cox of Bedminster sewed up a hide in the same position as it was on the animal's back, laced a canvas support round, and then filled it with ooze; and Mr Chaplin sewed his hide into a bag, filled it with ooze, but laid it in a reclining position, turning it periodically.

Seguin's process of tanning by solutions, although a great improvement upon the old method, is still tedious and expensive. Where warm oozes are used, it requires six or seven months for sole-leather; where cold oozes are in use, it extends to twelve months; consequently the tanner can turn his money only once a year: he must have capital enough to pay for twelve months' hides, bark, &c., labour, and contingent expenses, besides keeping a stock of leather; and when his capital has been turned at the end of twelve or more months, it must pay him, in one single profit, the interest, &c., of twelve months. This has confined the trade to a few wealthy individuals, who look upon tanning as an investment for capital rather than as a business which might be improved by science. Hence tanning has been more stationary than any other manufacture, and the few improvements which have been made in it have not been made by tanners. Another patent has occupied considerable attention. It is founded upon the principle adopted in washing a sponge. The old tanner takes his sponge (the hide) full, or nearly so, out of one ooze, and inserts it nearly full into the next. The patentees of the roller and belt system squeeze, by a simple and self-feeding press, their hide, before they drop it into the fresh ooze; and this

simple modification would seem to promise well for the improvement of the art of tanning. Messrs Herapath and Cox of Bristol, the patentees, say that, to tan 100 butts per week, they erect in a tanyard, capable of tanning 50 per week, six or eight large pairs of rollers, one pair over each pit. The lower roller is 30 inches in diameter, and is covered with horse-hair cloth; the top one 18 inches, with levers for weights, covered with woollen cloth. For each pair of rollers there are from 50 to 100 hides, connected together head to head and tail to tail, each by about four strings. Now the first butt or hide is inserted between the rollers loaded to the proper pressure; and upon turning the bottom roller (which requires very little force, as it is a slow motion), all parts of the butt are pressed as they are pulled through by the rollers; the next comes in order by the assistance of the strings; and so on, until the whole of the hides in the belt have been pressed, and deposited in the fluid on the other side of the pit. By a detent the motion is now reversed, when the belt is again pressed, and returned to its original position for a fresh supply of ooze

(see fig. 2). This simple plan brings strong ooze so frequently into the interstices of the hide, that the centre of a stout butt is not only stained through, but tanned, in between one and two months; calf-skins and kips are tanned in from twenty to thirty days; and the liquors are so rapidly exhausted,

Fig. 2.

that they are reduced from 45° to nothing in thirty-six days, losing at first more than 2° per day; and the shortness of this exposure to the air prevents much of the tannin from being decomposed. It was stated at the time when this patent was taken out, that at Nailsea, near Bristol, 100 butts per week were tanned, with six latches, six rolling pits, twenty-four handlers for the offal, and six layers; one horse-power driving the rollers, and two boys managing them. The following were given to us as the results produced in the first yard which was put entirely on the patent plan, as compared with those of the same yard on the old plan:—Double the work was done, and half the capital drawn out as useless. The saving on bark, labour, and general cost of manufacture was 1½d. per lb. The increase in the weight of butt leather was as 34 lb. to 28 lb.; 46½ lb. of leather being produced from a 60 lb. wet salted hide. The butts were sent to market within four months from the time the hides were delivered to the yard. The profits from quick return, great weight, and small expense, were eight times as great as on the old plan, at similar prices of hides, bark, and leather. The leather was also said to be more elastic, and more impervious to wet, than any other that is made. Notwithstanding all these brilliant results, the plan seems to have failed. An extended experience with the new method seemed to prove that the leather was more brittle, and in other respects inferior to that produced by the old method, which still continues in operation at most tanneries.

We must notice Bordier's method of making leather by means of metallic or earthy substances. The hides are washed, unhaired, and swelled as before, when they are immersed in a solution of sub-sulphate of peroxide of iron, or sulphuric acid, with excess of the peroxide. The solution

Leather.

Leather. may be prepared as follows:—2 cwt. of bruised sulphate of iron are dissolved in 15 gallons of boiling water, in a copper boiler. The solution is run off into a shallow vessel of the capacity of 4½ gallons, then 44 lb. of sulphuric acid, sp. gr. 1·848, are stirred in, together with 4½ lb. of black oxide of manganese in powder; but the latter must be added gradually, the whole being stirred up so long as gas is disengaged, and afterwards, at intervals, until the solution is cold. It may then be diluted with water to the required strength. By digesting hides and skins in this liquor, they become impregnated with an insoluble sub-sulphate of peroxide of iron, while there remains in the liquor free sulphuric acid, sulphate of manganese, and a small quantity of proto-sulphate of iron. It is stated that hides in the course of six or eight days, and skins in three or four days, become converted into leather, which is as impurescent and as impermeable to water, as leather tanned in the usual manner.

Splitting.—In the preparation of certain kinds of leather, the hides, after immersion in a weak ooze for from ten to fourteen days, are split into two portions, after which the halves are tanned separately. The upper, or grain half, is used for covering carriages, and the flesh half for enamelling. The principle of the machine used in the splitting will be understood by referring to fig. 3, in which D represents a

Fig. 3.

mahogany drum, 4 feet in diameter, and about 6 feet in length: the tail end of the hide or skin is fixed into a slot in the drum at *a*, by means of wooden wedges; *k* is a steel knife of the length of the cylinder, attached by means of screws *s, s'* to the bottom of a cast-iron carriage *C, c*. Rapid motion is given to the carriage by means of a crank, by which the knife is made to vibrate rapidly backwards and forwards in a plane parallel to the axis *A* of the drum. The hide *h* is kept flat to the cylinder by means of a thin plate of steel *B*, called a governor, placed in front of the knife, and, being pressed down by a weighted lever, smooths out the wrinkles. As the hide *h* is thus cut, one-half *f*, which is the split flesh side, passes over the knife, while the other half, consisting of the split grain side *g*, adheres to the drum. The thickness of the split may be regulated by means of a screw *I* at each end of the drum, which screw, acting upon a lever *LL*, raises or depresses the axis of the cylinder, and thus diminishes or increases the thickness of the split grain side of the hide.

Currying.—The skin of leather as it leaves the tanyard, is a comparatively rough article, and requires the manipulations of the currier in order to fit it for the shoemaker, the coach-maker, the harness-maker, and other numerous trades in which leather is employed. Let us suppose that a tanned calf-skin is to be prepared for use. It is first made pliable by soaking in water, after which it is shaved on the flesh side, whereby the loose rough portions are removed, and a tolerably smooth surface is produced. This operation is carried on at a beam or strong frame of wood, supporting a stout plank faced with lignum vitæ, and set vertically, or nearly so. The knife (fig. 4) is a double-edged rectangular blade, about 12 inches by 5 inches, with

a straight handle at one end, and a cross handle at the other, in the plane of the blade. The edges of this knife are first made very keen, and are then turned over so as to form a wire edge by means of the thicker of the two straight steel tools shown in fig. 5, which wire edge is preserved by drawing the thinner steel tool along the interior angle of the wire edge from time to time

Fig. 4.

as required, for which purpose the man holds this smaller tool between his fingers, together with the beam-knife. The skin being thrown over the plank, the man presses his body against it, and leaning over the top, holds the knife by its two handles, almost perpendicularly to the leather, and proceeds to shave it; shifting it from time to time, so as to bring all the parts under the action of the knife, and frequently passing a fold between his fingers to test the progress of his work. The skin is then placed in cold water, and removed to a mahogany or stone table, to which the wet flesh side adheres, and is worked with a tool called a stretching-iron, or slicker *S* (fig. 5), consisting of a flat rectangular piece of iron, copper, or smooth hard stone, fixed in a handle. With this tool, a man scrapes the surface of the skin, exerting a strong pressure with both hands, and dashing water upon it from time to time, by which means lumps and inequalities are made to disappear, the leather is equalized and extended, and the bloom is brought to the surface. The superfluous moisture is now *slicked* out, and a stuffing or *dubbing* of cod-oil and tallow is rubbed into both sides of the skin, but chiefly the flesh side, by means of a brush, or with the woolly side of a piece of sheep-skin. The skin is now dried in a loft, and as the water only evaporates, the dubbing sinks into the pores. A stove heat is sometimes employed for the purpose, and the neighbourhood is unpleasantly reminded of the fact, by the currier using shavings of leather as fuel. When dry enough for the purpose, the skin is *boarded*, or worked with a graining board or pommel *C* (fig. 5), the effect of which is to bring up the *grain*, or give a granular appearance to the leather, and

Fig. 5.

also to make it supple. The pommel is a piece of hard wood, grooved like a crimping-board, and attached to the hand by means of a strap, whence the word pommel, from the French *paumelle*, or palm of the hand. The leather passes through various manipulations, each having its distinct name; thus *graining* consists in folding the skin with the grain sides in contact, and rubbing strongly on the flesh side; *bruising*, or rubbing the extended skin on the grain side; *whitening*, or passing a knife with a very fine edge over the skin at the beam, so as to clean the flesh side, preparatory to *waxing*, which is done just before the skins are sold; for at this point the currier stores his skins, as they can be kept best in the state of *finished russet*, as it is called previous to waxing. Waxing consists of two parts: the first is the laying on the *colour*, or blacking of oil, lamp-black, and tallow, which is well rubbed in on the flesh side with a hard brush; secondly, the skin is black-sized with stiff size and tallow, laid on with a sponge or a soft brush, and thoroughly rubbed with a glass *slicker*, a finishing gloss being given with a little thin size. The curried skin is now said to be *black on the flesh*, or *waxed*, in which state it is used for the upper leathers of mens' boots and shoes. The

Leather.

Leather. leather which is curried on the hair or grain side, is called *black on the grain*, and is mostly used for the upper leathers of ladies' shoes. In preparing such leather, the waxing is performed as follows:—A solution of sulphate of iron, called *copperas-water*, or *iron-liquor*, is applied to the grain side of the wet skin, when the salt, uniting with the gallic acid of the tan, produces an ink dye; stale urine is then applied to the skin, and when dry, the stuffing is applied. The grain is raised, and when dry the skin is whitened, bruised, and again grained; after which a mixture of oil and tallow applied to the grain side, completes the process.

Varnished and Enamelled Leather.—For many years it was found difficult to cause a bright varnish to adhere to leather without cracking, an effect which is now produced by means of boiled linseed oil, mixed with vegetable black and Prussian blue. This composition, of the consistence of a thick paste, is rubbed upon the surface of the leather, and then dried at a temperature of from 150° to 170° Fahr. The process is repeated from three to seven times, and when quite dry, the varnish adheres very firmly, and will bear considerable flexure and tension without cracking. By mixing coloured pigments with the varnish, enamelled leather of various colours may be produced.

Thin Leather.—The process of tanning differs considerably in the mode of treatment with the kind of skin and the result desired. A large number of thin leathers which are intended to be dyed, are tanned in various ways. White leathers are not tanned but tawed, or treated with alum, salt, and some other matters. Wash leather is dressed with oil, or shamoyed. But whatever may be the subsequent treatment, the preparatory steps somewhat resemble each other, whereby hair, wool, grease, and other matters, are removed, and the skin is reduced to the state of a gelatinous membrane called *pelt*. The hair is removed from kid and goat skins, by means of cream of lime; the wool is generally removed by the fell-mongers before the skin is passed to the tawers. Foreign lamb-skins, which are received with the wool on, are washed, scraped on the flesh side, and sweated in a close room, until, in consequence of the putrefactive fermentation, the wool can be easily removed. After this, fatty matters are got rid of by subjecting the skins to hydrostatic pressure; they are next worked at the beam, and pared into shape, treated with lime, and next with dogs' or pigeons' dung if the skins are to be tanned, and with bran and water if they are to be tawed, the object being in either case to get rid of the lime. During these operations the skins are worked a few times at the beam, and are finished by washing in clean water.

Morocco leather is prepared by tanning goat-skins with sumach, and dying on the grain side. Inferior moroccos are prepared from sheep-skins similarly treated, for which purpose each skin of pelt is sewed up into a bag, the grain side outermost, distended with air, and placed in a mordant of tin or alum. They are next placed in a warm cochineal bath for red, indigo for blue, orchil for purple, and are worked by hand until the dye has properly struck. For certain colours the tanning precedes the dyeing. The tanning or sumaching is carried on in a large tub, containing a weak solution of sumach in warm water; another and stronger solution is contained in an adjoining vessel, a portion of which, together with some sumach leaves, is poured into the bag; some of the weak solution is then added, the bag is then distended with air, and the skin thrown into the vat. In this way about fifty skins are treated, and are kept in motion a few hours in the sumach tub by means of paddles worked by hand or by machinery. The skins are then taken out and heaped up on a shelf at the side of the tub, the pressure thus produced causing the liquor to escape slowly through the pores of the skin, the bags being shifted about from time to time. The bags are next passed into a second vat containing a stronger solution, where they re-

main for nine hours. The bags are now opened and washed; fine red skins being finished in a bath of saffron. All the skins are next *struck* on a sloping board until they are smooth and flat, and in order to improve their appearance in the currying a little linseed oil may be rubbed on the grain side. They are then hung up in a loft to dry, when they become horny, and are *in the crust*, as it is called. They next pass through much laborious friction with the pommel, and with a glass-ball; while the peculiar ribbed appearance of morocco is given by means of a ball of box-wood, on which is a number of narrow ridges. Sheep-skin morocco is prepared from split skins; the skin-splitting machine resembles in principle that already described, only as the membrane is thinner certain variations are required. Instead of stretching the skin on a drum, it is passed between two rollers, the lower one of gun metal and solid, and the upper made of gun-metal rings; while between the two rollers, and nearly in contact, is the edge of the sharp knife, which is moved by a crank, as already mentioned. When a skin is introduced between the two rollers, it is dragged through against the knife edge and divided, the solid lower roller supporting the membrane, while the upper one, being capable of moving through a small space by means of its rings, adjusts itself to inequalities in the membrane; where this is thin the rings become depressed, and where it is thick they rise up, so that no part escapes the action of the knife. The divided skins are not sewed up into bags, as from their thinness they can be sumached quickly.

In preparing white leather by tawing, the pelt is made as pure as possible; the best kid leather being prepared from kid skins, while sheep or lamb skins make the inferior kinds. They are first fed with alum and salt in a drum or tumbler made like a huge churn; about 3 lb. of alum, and 4 lb. of salt being used to 120 skins of medium size. The alumina of the alum probably forms some definite compound with the gelatine of the skins, while the salt serves to whiten them. When taken out the skins are washed in water, then allowed to ferment in bran and water, to remove the surplus alum and salt, and to reduce the thickness. They are next dried in a loft, and become tough and brittle, but they are made soft and glossy by means of a dressing of 20 lb. of wheat flour, and the yolks of eight dozen eggs. By rotating the skins in the drums for some time the dressing is absorbed, and scarcely anything but water remains. This dressing is usually repeated, and the skins are hung up to dry. The beautiful softness and elasticity of this leather is now given by manipulation. The skins are first dipped in clean water, worked upon a board, and staked upon a stretching, or softening iron, consisting of a rounded iron plate fixed to the top of an upright beam, by which the skins become extended and made smooth. They are finished by being passed over a hot iron.

When a skin, properly cleaned and soaked in water, has oil or grease forcibly rubbed into its pores, the oily matter combines with the fibres, and renders the skin permanently soft. Water only evaporates during the drying, and the result is a kind of leather called *chamois*, *shammy*, or *shamoyed*, from the fact that the skin of the *chamois* appears to have been the first treated in this manner. When such leather is dyed, it will bear washing, and hence it is also called *wash-leather*. The best leather of this kind in Great Britain is prepared from doe or sheep skin, while for inferior kinds the flesh side of a split sheep-skin is used, the grain side being tawed for *shiver*, such as is used for hat-linings, &c. Where the whole skin is employed, the grain is removed by *frizing* or scraping with pumice-stone or with a round knife. The skins are now placed in bran liquor, wrung out, spread upon a table, sprinkled with a small quantity of oil, rolled up into balls, four skins to the ball, and beaten with wooden hammers in fulling stocks. After two or three hours' beating they are

Leather.

Lebadea
||
Lecce.

taken out, exposed to the air, again oiled and beaten, which operations are repeated several times. After this the skins are hung up in a warm room, where they undergo a kind of fermentation which promotes the union of the oil with the fibre. They are next scraped with a blunt concave iron, scoured in weak lye to get rid of superfluous oil, washed in water, dried, smoothed, and made supple by means of the stretcher-iron or rollers.

By a variation of the processes of shamoying and tawing, a stout leather, well adapted for driving-bands for machinery, has been produced by Preller's process. The hides and skins being unhaird, &c., are smeared with a paste consisting of starch, oil or fatty substances, salt, and saltpetre, and are then agitated in a drum. After two or three smearings and agitations and drying, the process is complete. In a leather thus formed the fibre of the skin is preserved, and an increased toughness consequently gained.

Recent Improvements in Tanning.—The tanner has not of late years shared in the benefits which the rapid advance of chemistry has conferred on other arts. Mechanical improvements, however, have been introduced, such as the splitting-machine already referred to: the steam-engine is also generally used, and is applied in various ways for grinding bark, for softening foreign hides, and for giving motion to machines for washing, glazing, and finishing leather. The hydrostatic press is also in use for expressing the grease from sheep-skins, the effect of which is to allow the skin to take a more brilliant dye. The abolition of excise duties, improved

means of transport, and more liberal commercial relations with other countries, have all tended to the improvement of the leather trade.

Statistics.—The quantities of untanned hides imported into the United Kingdom during the years 1853, 1854, and 1855, were respectively, 231,761, 184,024, and 188,844 cwts. of dry hides; and 518,548, 417,175, and 426,933 cwts. of wet hides: while during the same years there were imported of hides tanned, tawed, curried, or dressed (except Russia hides), 7,286,602, 4,180,315, and 4,368,111 lb. Of leather manufactures, the principal article of import is gloves, which, during the three years above named, amounted to 3,476,341, 3,781,624, and 3,612,639 pairs. The next considerable article of import is boot-fronts, of which, in the year 1855, there were imported 538,604 pairs. Of men's boots and shoes there were only 33,115 pairs; of women's boots and goloshes, 26,975 pairs; of women's shoes of silk, satin, stuff, or leather, 111,054 pairs. During the three years above named, there were exported from the United Kingdom, of untanned hides, dry, 70,295, 94,562, and 123,309 cwts.; of wet hides, 15,521, 17,369, and 38,405 cwts.; while of tanned, tawed, curried, or dressed hides, the quantities were respectively, 29,746, 135,241, 338,422 lb. Of foreign leather manufactures, the only article of export is gloves, of which the number of pairs were respectively, 327,645, 390,987, and 217,458. During the three years above mentioned, the exports of British produce, in leather, were as follows:—

Lecco
||
Lectoure.

DESCRIPTION.	Quantities.			Declared Value.		
	1853.	1854.	1855.	1853.	1854.	1855.
Leather, unwrought	23,740 cwt.	29,601 cwt.	31,034 cwt.	L.195,525	L.250,370	L.256,678
Wrought, viz., gloves	31,214 lb.	34,102 lb.	28,420 lb.	25,250	28,312	21,151
Of other sorts	5,404,402 lb.	4,841,987 lb.	3,462,765 lb.	1,057,716	896,077	637,348
Saddlery and harness	300,104	329,614	226,662

The gross receipts of customs' duties on leather manufactures imported into the United Kingdom during the years 1853, 1854, and 1855 were respectively, L.58,427, L.61,497, and L.59,984. (C. T.)

LEBADEA, or LEBADEIA (modern *Livadhia*), a town of Bœotia, near the frontiers of Phocis, between Chæronea and Mount Helicon. It is famous as the seat of the oracle of Trophonius; and in the time of Pausanias it seems to have been the most prosperous city of Bœotia. The town was twice plundered by Lysander; and by Archelaus, the general of Mithridates.

LEBRIJA (the ancient *Nebriſsa*), a town of Spain, province of Sevilla, near the left bank of the Guadalquivir, and 29 miles S. by W. of Sevilla. Being situate in an extensive and marshy plain, the town is unhealthy, especially in summer. The manufactures are cloth, sackings, glass, earthenware, soap, bricks, tiles, &c. It has remains of an old castle of considerable extent. The parish church, built of the materials of an old mosque, is a mixture of the Arabic, Roman, and Gothic styles. Pop. 6300.

LECCE (the ancient *Lupia*), a town of Naples, province of Terra di Otranto, on the road from Brindisi to Otranto, about 22 miles distant from each, and 8 miles from the Adriatic. It is fortified by walls, ditches, and towers, and is farther defended by a castle or citadel. The space occupied by the town, it is said, would accommodate double the present population, and hence it has a rather deserted appearance. It is, however, one of the best built towns in the kingdom, having wide and regular streets, and many handsome buildings. The cathedral of St. Oronzio has a wooden roof richly carved and gilt. Lecce is the see of a bishop, and contains a royal college. It has manufactures of woollen, cotton, and silk goods, lace, and snuff; and

carries on an active trade in the products of the surrounding country,—silk, wool, flax, cotton, oil, wine, gum, &c. *Lupia* was an ancient Salentine city, said to have been founded by Malennius, a Salentine king. It is seldom mentioned as a Roman town, though it seems to have been a municipal town of some importance. Augustus remained there for some days on his return to Italy, after hearing of the death of Cæsar. No ancient remains are now visible, but they are said to have been numerous in the fifteenth century. Pop. about 16,000.

LECCO, a market-town of Austrian Italy, province of Como, on the Lago di Lecco, the S.E. branch of the Lago di Como, 17 miles E. by N. of Como. It contains about 5000 inhabitants, chiefly engaged in the manufacture of iron and copper ware, silk, cotton, and woollen stuffs; in which articles it carries on a considerable trade.

LECTISTERNIUM, a sacrificial ceremony observed by the Greeks and Romans on occasions of extraordinary solemnity, when the statues of the gods were placed in a reclining posture on couches, and a feast was spread on tables before them. This ceremony, according to Livy, was first observed in the year of Rome 354, on account of a destructive murrain among cattle. At first a distinction was made between the gods and goddesses, as at the *Epylum Jovis* held in the capitol, where the statue of Jupiter was laid in a reclining attitude, while those of Minerva and Juno were set on chairs. Afterwards this distinction seems to have been neglected, as may be inferred from a representation on the carved handle of a Roman lamp engraved by Bartoli.

LECTOURE (the ancient *Lactora*), a town of France, capital of a cognominal arrondissement in the department of Gers, stands on the summit of a steep isolated rock, near

Lecture
||
Lee.

the right bank of the Gers, 20 miles N. of Auch. The main street is wide, regular, and well built, but the others are irregular, dirty, and old-fashioned. The chief buildings are,—a handsome Gothic church, built by the English, an hospital, which occupies the site of the ancient castle, and the old episcopal palace, now the town-hall. Lectoure carries on a considerable trade in cattle, wine, brandy, and agricultural produce, and has some manufactures of coarse woollens, serge, and leather. It was long possessed by the Counts of Armagnac, the last of whom having revolted against Louis XI., was besieged in the town, and surrendered conditionally. The count, however, was faithlessly murdered, and the inhabitants massacred. Pop. (1851) 6030.

LECTURE, a name given to any discourse *read* by a professor to his pupils, but often applied to every kind of *viva voce* instruction. See UNIVERSITIES.

LEDA. See DIOSCURI.

LEDBURY, a market-town of England, county of Hereford, on a declivity near the Malvern Hills, 15 miles E. of Hereford. It consists, for the most part, of two streets, which cross each other. It contains an old parish church of Norman style, an hospital for the aged, founded 1232, and several chapels and schools. The manufactures are unimportant, consisting chiefly of ropes and sacking. A brisk trade, however, is carried on in hops, cider, perry, and limestone, the products of the neighbourhood. The Gloucester and Hereford Canal passes the town. Pop. (1851) 3027.

LEE, NATHANIEL, a dramatic poet, was the son of a clergyman, and born about the end of the seventeenth century. He was educated at Westminster School, and afterwards at Trinity College, Cambridge. After quitting the university, and remaining for some time an unsuccessful dangler about court, he began to write for the stage, and between 1675 and 1681 produced a new play every year. Poverty and a wild imagination, however, overturned his reason, and he was confined in Bedlam for four years. In 1688 he resumed his pen, and, though subject to recurring fits of insanity, he completed two plays between that period and his death, which happened in 1690, as Cibber says, during a night frolic in the street. In the latter part of his life he was dependent upon charity. Of his eleven tragedies, *Theodosius*, *Alexander the Great*, and *Lucius Junius Brutus* have alone taken a respectable position on the stage. His genius for tragedy, commended highly by Addison and other contemporary writers, is completely overborne by the wildness of his imagination, which often leads him into extravagant metaphor and turgid bombast. These faults, however, are partially redeemed by a graceful eloquence and true tenderness in describing the softer feelings of nature. Lee was an imitator of Dryden, whom he assisted in writing *Ædipus* and the *Duke of Guise*.

LEE, Rev. Samuel, D.D., Regius Professor of Hebrew at Cambridge, was born at Longnor, in Shropshire, 14th May 1783, and was educated at a charity school in that village. Apprenticed to a carpenter at the age of twelve, he began early to display that power of application which characterized him all through life, and at the age of seventeen, he commenced to study Latin, purchasing books with his scanty savings. To an intimate acquaintance with this language, the knowledge of Greek, Hebrew, Chaldaic, and Syriac, was soon afterwards added. In 1810 Archdeacon Corbett, hearing of his wonderful acquirements, obtained for him the mastership of Bowdler's foundation school in Shrewsbury. He entered Queen's College, Cambridge, in 1813, and took the degree of B.A. in 1817. In 1819 he became Professor of Arabic at Cambridge, and in 1825, Rector of Bilton with Harrowgate. He received the degree of B.D. in 1827, and became Regius Professor of Hebrew in 1831. Two years afterwards the degree of D.D., which he had

Leeches
||
Leeds.

obtained in 1822 from the University of Halle, was again conferred upon him by his *alma mater*. He died in 1852.

His principal works are the following:—*Events and Times of Visions of Daniel and St John*, 8vo, London, 1851; *Hebrew Grammar*, 1830; *Hebrew, Chaldee, and English Lexicon*, 1840; *An Inquiry into the Nature, Progress, and End of Prophecy*, 8vo, Cambridge, 1849; *The Book of Job, translated from the original Hebrew*, 1837.

LEECHES. See HELMINTHOLOGY; Fam. II., Gen. *Sanguisuga*.

LEEDS, a town of England, in the W. Riding of Yorkshire, the metropolis of the woollen manufacture, and, in point of population, only exceeded by London, Manchester, Liverpool, and Birmingham. Leeds is situate nearly in the centre of the W. Riding, in the wapentake of Skyrack, and in the pleasant and well cultivated valley of the River Aire. The surrounding country possesses much cheerful beauty; and the view from Woodhouse Moor, one of the most elevated parts of the borough, is not exceeded in any part of the Riding. For manufacturing and commercial purposes, the situation of Leeds is highly advantageous, especially since the introduction of railways. It is now the terminus of the two great lines from London—the Midland and the Great Northern—and is, besides, the terminus of the North-Eastern, and the Manchester and Leeds Railways; whilst it stands in close connection with the E. Riding, through the York and North Midland, and the Leeds and Selby Railways. It has also connection with Cheshire, through the London and North-Western Railway; and with Scotland, through the North-Eastern, *via* Darlington and Newcastle; and *via* Lancaster, with the western route to Carlisle and Glasgow. It has also canal transit to Liverpool by the Leeds and Liverpool Canal, and to Hull by the Aire and Calder navigation; these means of transit, combined with the railways, giving Leeds the highest facility for the transmission to the principal seaports of England of its various manufactures, and for receiving at the lowest rate of charge the various kinds of raw material used in those manufactures. Leeds is the centre of a great bed of iron and coal mines. All the advantages for the successful working of machinery are, therefore, within its reach, and hence it has become the seat of several important manufactures, especially woollen, flax, and iron and machine-making.

Though regarded as the capital of the great manufacturing district of the W. Riding, Leeds is not in its centre, but on its border. Eastward and northward the country is wholly agricultural. Westward and to the S.W., in all the valleys, and on all the hills betwixt Leeds and the long and high range that separates Yorkshire from Lancashire, the populous villages resound with the shuttle and the steam-engine. In this district is carried on a woollen manufacture of great extent and of considerable antiquity; a worsted manufacture of extraordinary vigour (a graft on the woollen manufacture); and latterly the iron manufacture, and machine and steam-engine manufacture, besides a manufacture of flax, which has sprung up within the present century, and now constitutes one of the staple trades of Leeds.

Cloth is the staple trade of the town, although the manufacture itself is not the leading one within the borough, being carried on, to a large extent, in townships out of the parish and borough of Leeds. In the town, however, the trade centres, and there the cloth is finally prepared for consumption, by what is technically termed finishing or dressing,—a department so distinct in Leeds from that of the manufacturer, that the persons respectively engaged in them know very little of the art practised by each other. In this respect the Yorkshire cloth trade differs essentially from that of the W. of England; the practice in the latter being for the manufacturer to conduct

Situation
and commerce.

Industry.

Leeds. the two operations of making and finishing the cloth within the same premises, and so to control and direct the entire process, from the sorting of the wool to the delivery of the finished cloth. Several firms in the borough of Leeds, conduct their business on the W. of England model; but, as the rule, the order of the trade is as follows:—The great bulk of the cloths sold in Leeds are produced either in the out-townships of the borough, or in the villages lying W. of Leeds, and principally in Pudsey, Farsley, Rawden, Yeadon, Horsforth, and Guiseley, which are all in other parishes, within an extreme radius of 10 miles from Leeds. The cloths so manufactured are sold in the unfinished or *balk* state to the merchants of Leeds, by whom they are put out to the cloth-dressers or finishers, whose special craft it is to raise the pile or nap on the face of the cloth, and to complete it for the purposes of the tailor and the final consumer.

A very large proportion of the business betwixt the manufacturer and the merchants is conducted in the cloth halls, which are held on Tuesdays and Saturdays from 9 to 11 o'clock. Of these halls there are two—the Coloured Cloth Hall, erected in 1758, and the White Cloth Hall, erected in 1775. Both are built in the form of a square, with double streets, each street having a double range of stands for placing the cloths, behind which the manufacturers take their place, and invite the merchants to purchase. The whole length occupied by these stands is very considerable; and in the two hours during which the halls are open on the market-days, the amount of business transacted is exceedingly large. Within the last 20 or 30 years, however, a great change has taken place in the method of transacting business betwixt the manufacturer and the merchant. The latter orders goods of specific weights, colours, and qualities of the former, and these are delivered direct to him, without being exhibited in the halls. It is, in fact, very probable that more cloths are now made and delivered direct to order, than pass through the halls. The large manufacturers of the surrounding villages very rarely take stands in the halls, their principal business being a direct one with the merchant. At one period it seemed probable that the business of the cloth trade would assume the West of England type. Mr William Hirst, a very skilful manufacturer, introduced goods of superior texture and quality, and by his success induced many capitalists to erect mills on a large scale, in which all the processes of the manufacture and finishing were conducted. The change was, however, only temporary. Many of these mills are now occupied for finishing only, and some have been devoted to other branches of the local manufactures. This economy of the cloth trade seems likely to continue some time yet. If the spinning and weaving of woollen goods by power should become practicable to the extent now practised in the manufacture of worsted and cotton goods, there would, of course, be a great alteration in the entire economy of the trade. But there are peculiarities in the formation of the woollen thread which have baffled, hitherto, the ingenuity of the mechanist to meet by mechanical appliances only. Hence, the old hand-jenny, and the hand-loom continue in extensive, and, indeed, preponderating use, in the woollen trade, though they have been almost superseded in the other textile manufactures.

The spinning of flax by machinery was commenced in the township of Holbeck (in the borough of Leeds), more than eighty years since, by Mr John Marshall, who was one of the first to apply the principle of Sir Richard Arkwright's water-frame, invented in the cotton manufacture, to the spinning of linen yarn.

The works of Messrs Marshall and Company are very extensive, and one portion of them is an object of attraction to all strangers visiting the town. It is a vast room, 400 feet by 220, filled with machinery, all of which is turned by shafting, which requires two coupled engines of 350 horse

power to impel it. The building is lighted by glass cupolas, which admit of ventilation, and in summer are shielded by linen blinds. The whole building is held together by a double series of iron ties, uniting the iron pillars which sustain the many-arched roof. The external form is Egyptian; perhaps the only instance of the adaptation of the style and hieroglyphic symbols of Egypt to the purposes of manufacture presented in any part of Europe.

The spinning of worsted yarn and the weaving of worsted goods were, twenty or thirty years ago, carried on to a considerable extent in Leeds, but have now nearly died out; Bradford, Bingley, and Keighley, with the villages immediately adjoining, having attracted almost the entire trade. The mercantile department of the trade, technically called the stuff trade, long remained more extensive in Leeds than in Bradford, even after the latter town had all but monopolized the manufacture. Within the last ten years, however, nearly all the stuff merchants transferred their establishments to Bradford, though still continuing to reside in Leeds. The stuff trade of Bradford, notwithstanding, is still largely connected with Leeds, the wool-staplers and dyers of the latter having extensive dealings with the manufacturers and merchants of the former town. It is, indeed, probable that more persons are now thus employed in Leeds in this indirect connection with the stuff manufacture, than were ever employed directly in the spinning and weaving of worsted stuffs.

Amongst the smaller branches of the textile manufactures carried on in Leeds, must be enumerated those of silk and carpeting, neither of them unimportant, though falling far short of the flax and woollen trades.

The establishments for the casting of metals, the manufacture of steam-engines, and of machinery of every kind, are on a large scale; and it has, besides, establishments for the manufacture of mechanical tools, which won considerable premiums at the last Paris Exhibition. It is by no means improbable, that the various branches of the forging and casting of iron, and the manipulation of that most important metal into machines and engines for the manufacture of the various fabrics which minister to modern luxury, may before long constitute a more important branch of the local industry than the old and staple manufacture of woollens.

In addition to these principal branches of manufacture, Leeds produces largely in nails, tobacco, snuff, pottery, and glass.

The number of persons employed in mills within the borough of Leeds in 1835, as given by Mr Baker, sub-inspector of factories, was—woollen, 9312; flax, 5926; worsted, 1420. By the census of 1851, those employed in woollen and worsted manufactures amounted to 13,231 males, and 5112 females—total, 18,343; in flax manufactures, 2464 males, and 6722 females—total, 9186; machine-makers and workers in metals, 5734. The total number of persons engaged in some employment was 83,465, out of an entire population of 172,170. Of 38,468, the number of males under twenty years of age, 12,626 were employed; of 45,246 males above twenty, there were 41,886; of 38,987 females under twenty, 9682; and of 49,569 females over twenty, 19,321. These numbers show a very active condition of the industry of the borough. They show, also, that the proportion of males under twenty, and of females, who follow some occupation, is not so great in a large manufacturing borough like Leeds as is commonly believed; especially when it is considered how very large a proportion of the females who are returned as following some occupation are domestic servants. Out of the 19,321 females above twenty engaged in some occupation, 12,959 are either domestic servants, or follow some trade or employment in their own dwellings; leaving only 6362, or about 22 per cent. of the females of the operative class above twenty years of age, who follow out-door employments, chiefly in the mills.

Leeds.

The mechanical and other appliances of industry in the town of Leeds are on a large scale, as evidenced by the number of chimneys that crowd the view, belonging to mills, foundries, dye-houses, and machine and steam-engine establishments. Steam-power is universally employed where practicable; and the whole effective steam agency employed in Leeds is probably not less than 12,000 or 15,000 horse-power.

Religious statistics.

The census of religious worship of 1851 supplies the following particulars:—

	Places of Worship.	Total Sittings.	Appropriated.
Church of England.....	36	25,436	10,193
Independents.....	11	8,305	6,255
Baptists.....	13	5,781	3,981
Society of Friends.....	1	1,100	...
Unitarians.....	3	1,240	550
Wesleyan Methodists.....	26	20,475	12,871
Methodist, New Connection.....	7	2,717	2,075
Primitive Methodists.....	13	3,900	2,293
Wesleyan Association.....	10	4,354	2,916
Do. Reformers.....	4	200	...
New Church.....	1	850	700
Brethren.....	2	250	100
Isolated Congregations.....	5	280	...
Roman Catholics.....	2	1,220	820
Jews.....	2	140	50
Latter-Day Saints.....	1	240	...
Total.....	137	76,488	42,804

The supply of sittings is, in relation to the population, 46 per cent. The extension of religious appliances during the last fifty years has more than kept pace with the progress of the population. The extent of Sabbath-school instruction in Leeds is as follows:—

	Schools.	Scholars.
Church of England.....	46	9,292
Independents.....	14	2,894
Baptists.....	11	1,881
Wesleyan Methodists.....	31	6,387
Primitive Methodists.....	10	1,388
Wesleyan Methodist Association.....	11	2,226
Other denominations.....	24	4,693
Total.....	147	28,761

Education.

The appliances for general education taken from Mr Mann's able report to the Census Commissioners are as follows:—

Public Day Schools.	Schools.	Scholars.
Workhouse and military schools.....	3	485
Collegiate and grammar schools.....	2	242
Other endowed schools.....	7	635
Denominational Schools,—		
Church of England.....	35	6,892
Other denominations.....	28	4,922
Private day schools.....	295	8,658
	371	21,834

Literary institutions.

The preceding figures, in reference to day and Sunday-schools, show that the proportion of day scholars to population is one in 7·8, and of Sunday scholars one in 6.

The educational means of a higher order, and for literary and scientific purposes, in Leeds, are extensive. The Old Library, founded in 1768, at the recommendation of the celebrated Dr Priestley, contains a very valuable selection of books. The New Subscription Library is on a smaller scale, but is, nevertheless, a very useful institution. Besides these, there are several small libraries, chiefly connected with the several religious bodies in the town. In connection with the Leeds Literary and Philosophical Society, established in 1820, occasional lectures are given both by members of the society and by public lecturers. The building contains a laboratory, lecture-room, and a museum, with many fine specimens in natural history, geology, and

Leeds.

antiquities. The Leeds Mechanics' Institute, established in 1825, was originally limited to the purposes of a library, and supplying evening instruction in arithmetic, mathematics, and mechanical and chemical science. The institute was largely indebted to the liberality of the late Benjamin Gott, Esq., and John Marshall, Esq., for a valuable donation of books on literary and scientific subjects. In 1842 it was united with the Literary Society (founded 1834), under the title of the Leeds Mechanics' Institution and Literary Society. By means of an exhibition in 1839, and again in 1842, the Mechanics' Institute had become possessed of a handsome building, originally built as a music saloon. The principal room (the upper one) serves all the purposes of a lecture, reading, and news room and library. By the union of the societies, an excellent collection of books has been formed, and the number of newspapers and periodicals provided is very large. There are day and evening classes in connection with the society, and the curriculum of the education given is of a high order. The School of Art, originally established by the government, is also an adjunct of the society, and is well frequented. The number of members of the literary department solely, was in 1856, 1776; and of boys and others in the day and evening schools, 258. The income of 1855 was L.1700, allowing a very frequent supply of lectures, &c. The institution is in a very flourishing condition. Besides this one central and principal mechanics' institute, there are many subsidiary ones in the out-townships, and in various parts of the township of Leeds. Within the last two years also, a Young Men's Christian Institute, much on the model of the Literary Institution, has been founded, and already numbers 500 subscribers.

Charities.

Of the charities of Leeds, the older are chiefly the dwellings for aged widows, now tastefully rebuilt, and the "Pious Use Property." The annual income of the several endowed charities is about L.5000.

The Infirmary, established in 1767, and finally completed in 1792, stands near the Coloured Cloth Hall. It is a large but plain building of red brick, forming three sides of a quadrangle, and with a large open space laid out in walks and flower-beds, to which the late Richard Fountayne Wilson, Esq. added a munificent grant of 4000 yards, thus leaving a clear and open space down to the Wellington Road. The House of Recovery was opened in 1804, but, being in an unfavourable locality, a new building was erected in 1840, near the present Industrial School, in a very salubrious neighbourhood, and, from the style of the architecture, constituting it an ornament to the town. Besides these are the Benevolent or Stranger's Friend Society, the Dispensary, the Eye and Ear Infirmary, the Church Visiting Society, and the Leeds Guardian Society.

The town and borough of Leeds was incorporated by The municipal letters patent, 2d Charles I., but this charter was cancelled or surrendered. A new charter was granted, 13th Charles II., under the style of mayor, aldermen, and burgesses of the borough of Leeds. The corporation consisted of a mayor, twelve aldermen, twenty-four assistants, and a staff of thirteen officials. The Municipal Act of 1834 gave Leeds a corporation of sixteen aldermen and forty-eight councillors, which has effected great improvements in the management of local matters. In addition to the powers granted to it by the Municipal Reform Act, the town council has acquired, through successive improvement acts, extensive control over the construction of dwelling-houses, the height of rooms, and the width of streets. It has large power to enforce the consumption of smoke, and to determine the height of furnace and engine chimneys, and for the abatement or removal of nuisances of every kind. The corporate expenses for 1856 amounted to upwards of L.25,000.

The management of the highways in the township of

Leeds. Leeds is in the hands of a board of highway surveyors, having under their charge twenty-two miles of paved streets, and ten miles of roads, and who expended, in 1855-56, L.6809. The administration of the poor law in the township of Leeds is in the hands of a board of guardians. In the out-townships, the overseers levy, collect, and administer the rate. The expenditure, in 1855-56, for the township of Leeds, was L.26,693, 5s. 8d., a very small amount, considering the population, and considerably less than in many former years; the amount paid in 1843 being L.31,982 7s. 2d., and, in 1848, L.40,784, 16s. 3d. The aggregate annual charge of public rates, estimating the poor and highway rates of the out-townships at L.10,000, does not fall far short of L.95,000 to L.100,000 per annum. The rates are, in fact, between 6s. and 7s. in the pound on the assessed rental of the borough,—the assessed rental being taken at $\frac{1}{4}$ ths of the actual rental. The supply of water for the township of Leeds is under the management of the town council, who, in virtue of a power reserved to it when the Leeds Water Works Company was incorporated in 1837, have assumed the property of that company. The capital thus assumed, and which is all raised on mortgage given by the town council on the property, is L.270,031, 14s. 9d.; which will be further increased by the works at Arthington, on the River Wharfe, ten miles from Leeds, from which an additional supply of 2,500,000 gallons per day can be obtained. The water is to be pumped from the river by steam power into reservoirs at Arthington, and from thence forced by steam power also, through iron pipes of large diameter, to the reservoir situate at Eccup, a small village 6 miles N. from Leeds. This extension is estimated to cost L.14,000. The supply of water from the existing works being 1,600,000 gallons; the total supply after Arthington Works come into operation will be 4,100,000 gallons per diem. Leeds is supplied with gas by two companies, having an aggregate capital of L.224,487. The value of the gas annually supplied is upwards of L.50,000; or, including the gas manufactured by mill-owners for the use of their mills, about L.55,000.

Places of
amuse-
ment.

Of the places of recreation in Leeds, the principal is the Music Hall, built in 1792. It is a plain structure, and is used far oftener for public meetings than for musical performances. The New Town Hall, provided with an organ and orchestra, it is expected, will almost entirely supersede the Music Hall, which has no organ, and is besides much too small. The Assembly Rooms, over the north end of the White Cloth Hall, were opened about 1780, and are not much used. There are two theatres, and a casino. The Royal Gardens, situate at Headingley, 2 miles from Leeds, in a delightful locality, were originally laid out for botanical and zoological purposes, but are now converted into a place of public amusement. The place of largest public resort is Woodhouse Moor, a bare common N.W. of Leeds, and about a mile from the centre of the town. It is an elevated spot, and commands an exceedingly fine view S. and W. In the summer evenings it is generally thronged with cricket-players, norr and spell players, and others in quest of healthful amusement.

Public
buildings.

The external appearance of Leeds has been greatly improved within the last twenty or thirty years. At the commencement of the century it had only one plain stone bridge over the Aire, now it has six new ones within the borough, two of which are of stone and four of iron, and by no means inelegant structures. The railway approaches and termini have greatly altered the appearance of the place. The latter, though on a large scale, have not yet (1857) assumed the form finally contemplated. The streets of Leeds, under the operation of the Improvement Act, have undergone large alterations, and, since the new sewer was constructed, at a cost of L.150,000, are laid down with a pavement of great strength, and with causeways of

the amplest dimensions. Within the present century an unsightly pile of buildings, including the old Moot Hall, or Court House, has been removed from the northern end of the principal street, Briggate; as also has the old Market Cross; and although the shops and houses are many of them of a remote date and very paltry, the whole view of the street is imposing. Under the Act of Improvement obtained 1856, the town council are empowered to open up a new and spacious street from the front of the New Town Hall to Wellington Street. The greatest change hitherto produced in the town has arisen from the erection of public markets, the rebuilding of churches and chapels, and other public edifices, and its rapid extension of houses west and north, in which quarters the houses have been built in a style far surpassing that of the older portions of the town. Leeds has four market-places—the Leather or South Market; the Central Market, which is, in fact, a great cluster of shops; the Covered Market, in the Vicar's Croft (just completing), for vegetables, &c., at a cost of L.14,000; and an extensive cattle and sheep market, on a very extensive scale, in the North Town End. The parish church is a very ornamental structure; some of the other churches are also in an excellent style of architecture. There is also a jail, erected at a cost of L.43,000.

The Town Hall is a parallelogram of 250 feet by 200, and 65 in height, of Corinthian architecture. The Great Hall is the largest room in England, except that of St George's Hall, Liverpool. It is 161 feet long, 71 feet wide, and 73 feet high, and is calculated to hold 8000 persons. The orchestra is placed at the north end. The town council have voted L.5000 for an organ, and L.8500 for the purpose of erecting a tower or dome over the vestibule. When the new street is opened from this point to Wellington Street, the view in ascending from the latter will be very striking. A large bronze statue of the Duke of Wellington is already placed in the front area, and will be flanked by a statue of Sir Robert Peel, in the same material, which now stands at the south angle of the present court-house. A statue of the late Edward Baines, Esq., formerly M.P. for Leeds, will also be placed in some suitable part of the building, or in the area. These statues were erected by public subscription, at an aggregate cost of upwards of L.4200.

The history of Leeds has been written by two antiquarians—Ralph Thoresby, F.R.S., a learned and pious native of the town, who published his *Ducatus Leodiensis* in 1714, and the Rev. Thomas Dunham Whitaker, LL.D., F.S.A., who republished Thoresby's work and added another volume, under the title of *Loidis and Elmete*, in 1816. The latter work deserves high praise for its ability and antiquarian learning; but it is miserably deficient in its notice of the trades and manufactures of the place, and treats them with the most prejudiced contempt. More recently the civil, ecclesiastical, literary, commercial, and miscellaneous history of Leeds, and the surrounding towns and villages, has been written by the late Rev. Edward Parsons, of Halifax, in 2 volumes—a work which brings down, very completely, the history of Leeds to the year 1834. A more recent work by James Wardell, Esq., deputy town-clerk of the town of Leeds, brings down the municipal history of the borough to the year 1846. Both these works are of great value to the historian and antiquarian; but it is no disparagement to the authors to say, that the changes produced by the repeal of the Corn Laws, the adoption of railway transit, and other social and municipal changes in the laws, have rendered necessary a new history of Leeds. It is difficult to realize the contrast betwixt the Leeds of 1832, the time of the passing of the Reform Bill, and Leeds as it now is; and it is quite possible that ten years hence the historian of Leeds may smile at the modest tone in which Leeds, commercially and nationally, is now spoken of.

Leeds.

Leek
||
Leeward
Islands.

Leeds has been distinguished for the last sixty years by the energetic action of the public generally, on all political questions, including the slavery question, Reform Bill, Catholic Emancipation, repeal of the Corn Laws, repeal of the Test and Corporation Acts, and the repeal of the East India monopoly. The newspapers published in Leeds are, the *Leeds Mercury*, an influential journal published three times per week; the *Leeds Times*, more radical in its tone than the *Mercury*; and the *Leeds Intelligencer*, which is Conservative.

The borough and parish, which are co-extensive, measure in their longest diameter upwards of 7 miles, with a circumference of 30, cover 21,470 acres, and comprise, besides the township of Leeds (properly so called) ten out-townships, nearly all engaged in the staple manufactures of woollen cloth, flax, or iron. Chapel Allerton, Potternewton, and Headingley are, however, mere suburbs of Leeds, a very large proportion of the inhabitants of those townships being persons whose places of business are in the town of Leeds. The population of the township of Leeds, and of these ten out-townships, in 1851, was as follows:—Leeds township, 101,490; Armley, 6190; Beeston, 1973; Bramley, 8949; Chapel-Allerton, 2842; Farnley, 1722; Headingley, 6105; Holbeck, 14,152; Hunslet, 19,466; Potternewton, 1385; Wortley, 7896—total, 172,170.

The value of real property in the borough of Leeds assessed in 1843, consisting of lands, houses, tithes, quarries, mines, and ironworks, was L.342,937, 9s. 10d.; or, including the out-townships, L.544,272, 1s. 1d. The present value is probably about L.626,000.

The census of 1851 showed that there were 36,165 inhabited houses in the borough of Leeds, 1646 uninhabited, and 259 building. Since the passing of the Reform Act, Leeds returns two members to parliament. (T. P.)

LEEK, a market-town of England, county of Stafford, on an eminence above the Churnet Water, an affluent of the Trent, 31 miles S. by E. of Manchester, by railway. The only public buildings are, the parish church, erected in 1180, the town-hall, and chapels. The silk manufacture has long been carried on here in its various branches of silk thread, buttons, ribands, handkerchiefs, &c. Market days, Wednesday and Saturday. A navigable cut from the Caldon and Uttoxeter Canal approaches to within a short distance of the town, while by railroad it has communication with all the manufacturing districts of central England. Coal and lead are found at Bluehills, in the neighbourhood, the former in considerable quantities. Pop. (1851) 8877.

LEER, a town of Hanover, landdrostei of Aurich, on the Leda, about a mile above its junction with the Ems, and 14 miles S.S.E. of Emden. Vessels of 150 tons burden come up to the town, and hence a considerable traffic is carried on, chiefly in agricultural produce. Chief manufactures, linen, hosiery, soap, beer, vinegar, and brandy. Pop. 6500.

LEEWARDEN, a town of Holland, capital of the province of Friesland, on the Ee, and on the great canal uniting the Zuider Zee and the Ems, 32 miles W. of Groningen. It is surrounded by an earthen rampart and ditch, and is intersected by numerous canals, the banks of which, and the ramparts, being planted with trees, and forming agreeable promenades. The town is well built, and is the seat of a large trade. The chief manufactures are linen goods and paper. Among its public buildings are the town-hall, the palace of the Prince of Orange, exchange, house of correction, several handsome churches, and a Jewish synagogue. Pop. (1854) 24,461.

LEEWARD ISLANDS, a name frequently applied to those of the West India Islands lying between N. Lat. 15. and 19., and W. Long. 60. 30. and 65. 40. The group comprises the British possessions of Antigua, Dominica,

Montserrat, Nevis, St Christopher's, Anguilla, Barbuda, and the Virgin Islands, which are all included under one government. The French, Dutch, Danes, &c., have also possessions in the group. There are twenty-three islands, besides numerous islets, having in all an area of about 1700 square miles, and a population of about 321,000.

LEFKOSIA, the capital of Cyprus. See NICOSIA.

LEGATION. See DIPLOMACY.

LEGATUS, amongst the Romans, an ambassador, or lieutenant-general. Legati were of three kinds,—1, Those sent by foreign nations on an embassy to Rome; 2, Those sent from Rome on an embassy to foreign countries or the provinces; 3, Those who served under Roman generals during war, or under the proconsuls and prætors in the provinces.

1. Foreign ambassadors, on approaching Rome, sent into the city the name of their nation, and the object of their embassy. If they came from a hostile people, they were either obliged to leave Italy unheard, or were admitted to an audience from the senate, who assembled for that purpose in the temple of Bellona, without the city. If their nation was friendly, they were received into the city, and deposited their names with the quæstors at the temple of Saturn. If they were persons of distinction, or came from an ally, one of the inferior magistrates, sent by the senate, met them on their landing in Italy, and accompanied them to Rome. All ambassadors were treated as public guests, and considered inviolable.

2. A Roman ambassador was elected by the senate from persons of high rank only; had the sacred character of a priest, and the power of a magistrate; was supported at the public expense during his journey; and if he died during his embassy, was honoured with a public sepulchre.

3. A lieutenant-general was generally a person of high military skill, and was appointed by the consul, prætor, or dictator, under whom he was intended to serve. His nomination, however, was not legal until sanctioned by the senate. His duty was to aid his superior officer, by advising him in all great emergencies, by acting as his substitute, both in civil and military affairs, and by assuming his insignia, as well as authority, during his absence. In the last case, he was called *legatus pro prætore*. The number of legati under one superior differed in proportion to the importance of the war, or the extent of the province.

LEGENDRE, ADRIEN MARIE (1752–1833). See SIXTH DISSERTATION, § 95.

LEGHORN (Italian *Livorno*), a free seaport-town on the W. coast of Italy, grand duchy of Tuscany, is situated at the extremity of a low and partly marshy plain, in N. Lat. 43. 32. 40., and E. Long. 10. 20.; 12 miles S.S.W. of Pisa, 54 miles W. of Florence by railway, and 85 miles S.E. of Genoa by sea. It is built nearly in the form of a square, surrounded by walls, with five gates, and intersected by regular, wide, and well-built streets. The old town of Leghorn, fronting the harbour, was long separated from the newer portions by a wall, and hence the streets here are narrower, and the buildings more crowded than in other parts of the town. It is traversed, however, by the noblest avenue in the city, the Via Grande, a wide street stretching from the Arsenal to the Pisa Gate, and having a large square in its centre, where many of the public offices are situated. To the N. and N.W. of the old town is what was formerly a suburb, called New Venice, but now incorporated with the rest of the city. It is intersected with canals, by means of which the various merchants' warehouses are supplied with their goods direct from the harbour. On the other side of the old town, to the S. and S.E. of it, a new part, now also included in the city, contains many elegant streets and mansions, the residences of the more opulent merchants. Leghorn cannot boast of

Lefkoria
||
Leghorn.

Leghorn. many fine edifices. Those most worthy of notice are as follow:—The Duomo, or cathedral, the oldest church of the town, standing in the Piazza Grande. There is nothing remarkable in its architecture, while its accommodation is so limited that a new and larger cathedral has been commenced, to supply the want. The Tower of Marzocco, or painted lion; the palace of Count Lardarel, containing a valuable collection of paintings; and the statue of Ferdinand I. de Medici, which stands close to the quay. Besides these, there are several parish churches, two Greek churches, a rich Jewish synagogue, and an English Protestant place of worship. Of the convents, the most famous is that situate on Monte Nero, which has in its possession a portrait of the Virgin, said to have floated from the island of Negropont to the Italian shore, unscathed by the violence of the sea. Water is brought into the town by a great aqueduct from Colognole, 12 miles distant. The accommodation of the harbour, however, is not in keeping with the size and importance of the town. Although possessed of two quays, neither of them have sufficient depth of water for large vessels, nor room for all those which are able to enter. This has been caused partly by the great quantities of sand washed in by the Mediterranean, and partly from want of due care on the part of the authorities. The port possesses two harbours. The outer and larger one is protected by a stone pier about 3000 feet long, and can be entered by ships of about 100 tons; while the inner harbour, which stretches into the town, has been so filled up that it is used only by small craft, and as building and repairing docks. A new harbour is, however, in course of construction south of the present one, and, when completed, will have sufficient depth of water for the largest vessels. At present large ships have to discharge their cargoes in the roadstead, which lies between the shore and a sandbank W.N.W. of the harbour, 4 miles in length by 2 in breadth, and having from 3 to 18 feet of water over it. The hold is good, and every facility is afforded for landing goods and passengers by means of lighters. A lighthouse, standing on a rock close to the mole, is seen many miles at sea. The lazaretto accommodation here is unequalled in Europe. There are three houses, for vessels with clean, foul, or *compromised* bills of health respectively.

The trade of Leghorn has been for many years in a flourishing condition, greatly owing to the privileges extended to the port by the Tuscan authorities; for, with the exception of the few government monopolies, goods can enter here more cheaply than perhaps at any town on the continent. Indeed, in some cases, articles of British manufacture are to be had in Leghorn at a lower rate than in England itself. But, besides the port privileges, the municipal laws are so framed that persons of all creeds and religions can live here in the enjoyment of their respective religious services. The English cemetery of Leghorn—the resting-place of Smollett and others known to fame—was long the only Protestant burying-ground in Italy. The effect of these wise measures is manifest in the number and variety of the shipping which resort to this port. There are annually about 4000 vessels, with about 400,000 aggregate tonnage, entering its harbour, while the clearances are nearly the same. Of these, the largest number are Italian coasters. The others, in the order of the importance of their trade, are British, French, Greek, American, Austrian, Spanish, Dutch, Swedish, and Ottoman ships. The articles of trade are numerous, Livorno being the great emporium of Tuscany and the adjacent states. Its articles of export and import comprise all the Italian products and manufactures, such as argol, borax, grain, fish, straw hats, hemp, olive oil, rags, seeds, silk, skins, marble, tallow, timber, wool, vermicelli; and macaroni. Besides these, the articles peculiar to the Levant and N. coast of Africa for many years found their way to Western Europe, in great part, by way of Leg-

horn; but, as of late the British and American traders have gone direct to these parts, this traffic has fallen off, and that of the Peninsula become the staple trade. The following table of the chief imports into Leghorn, during the three years 1850, 1851, 1852, is taken from Macculloch's *Commercial Dictionary*:—

Chief Imports.	1850. lbs.	1851. lbs.	1852. lbs.
Coffee.....	3,023,000	4,439,000	3,610,000
Cotton.....	211,500	650,700	138,900
Indigo.....	275	259	384
Pepper.....	298,500	635,000	836,000
Sugar, Brazil.....	602,000	135,000	89,000
... Crushed.....	13,374,000	7,536,000	15,132,000
... East India and Santos..	1,512,800	129,000	966,000
... Havanna.....	3,400,000	1,149,000	2,510,000
... Loaf.....	18,500	6,000	37,000

The next table shows the quantity and value of the principal articles exported from Tuscany to Great Britain in the years 1853 and 1854, from the *Government Report of Trade and Navigation*:—

Principal Exports to Britain.	Quantity. 1853.	1854.	Computed Value. 1854.
Anchovies..... lb.	223,062	222,966	5,972
Boracic Acid..... cwt.	20,768	23,709	106,691
Corn, all kinds..... qr.	46,081	9,275	33,389
Marble, manufactured cwt.	4,555	8,863	11,079
... rough..... solid ft.	70,510	106,601	66,627
Olive Oil..... tuns	1,474	885	68,853
Rags for Paper..... tons	996	2,002	51,051
Seeds, Flax and Linseed..... qr.	3,256	20,650	63,240
Skins, Lamb and Kid, undressed..... No.	1,237,138	934,984	46,839
Straw, articles of..... lb.	43,664	26,796	38,068
Vermicelli and Macaroni..... cwt.	1,444	1,607	3,750
Wheatmeal and Flour cwt.	70,291	55,594	60,690

The total value of the imports into Leghorn, during the years 1852–3, and 1854–5, commencing October 1, was, in the former year, L.4,508,000, and in the latter, L.5,690,000; while the total value of exports for these years was L.2,848,800 and L.3,120,000 respectively. In 1856 there were 112 vessels, with an aggregate burden of 27,059 tons, and 414 small craft, with an aggregate of 7879 tons, belonging to the port.

The early history of this city is, to a great extent, enveloped in obscurity. The first mention we have of it is by Cicero, who calls it *Labro*. It was, however, in his time, and for many centuries after, but an insignificant fishing station, situate about 4 miles to the S. of Portus Pisanus, which then occupied the commercial position now held by the modern Livorno. In the fifteenth century it acquired its first importance as an Italian seaport, after having passed from the hands of the French to the Genoese, and from them to the Florentine Confederation. A harbour was constructed by the latter immediately after their acquisition, and town walls built. Stronger and more extensive walls were commenced in the year 1577 by Francesco I., and public buildings were afterwards erected by his successor, Ferdinand I. This wise ruler was, in reality, the great founder of the Livorno trade. He was the first to pay no respect to creeds or religions; but, on the contrary, invited all those who were anxious to prosecute commerce honourably and with perseverance, whether they happened to be Roman Catholic, Protestant, Greek, Jew, or Mohammedan. Under his liberal government the port of Leghorn became the only town where freedom of opinion was recognised, and formed a leading principle at that time. From the end of the sixteenth century until the year 1796, when the town was taken by the French, its trade and commercial relations increased and extended; but with the French occupation commerce and freedom were virtually at an end. After the conclusion of peace, however, in

Legion
||
Leibnitz.

1814, the port recovered its traffic, and has now gained the highest position as a seaport in the Peninsula. Its progress was slightly checked during the revolution of 1848 and 1849, when the Austrians seized it, and occupied it for some time, a proceeding which, fortunately, had a less prejudicial effect on the trade than might have been expected. The custom-house officers were more strict in searching vessels for arms, but otherwise traffic was not impeded.

The manufactures of Leghorn are unimportant. Those most worthy of mention are ropes, woollen caps, alabaster and coral ornaments. Many boats belonging to the port are sent annually to the coral fisheries off the coasts of Sardinia and Barbara. There are several mineral springs in the neighbourhood of the town. Pop. (1855) 79,962, many of whom are Jews. The government, or province of Leghorn, including the island of Gorgona, has an area of 24,320 acres, with a population of 92,200 persons.

LEGION. See *Roman Army*, under ARMY.

LEGITIMACY. See PARENT AND CHILD.

LEIBNITZ, GOTTFRIED WILHELM, was born at Leipsic on the 3d of July 1646. At the age of six he lost his father, Frederic Leibnitz, the Professor of Ethics in the University of Leipsic, from whom he inherited a considerable fortune and a valuable library. The latter part of his heritage proved the more useful, for with its aid he may be said to have educated himself, although he attended from his early years the Nicolai School of his native city. Impatient of the slow progress at school, he began to read in private all the Latin and Greek authors that fell in his way, with so much profit, that before he was twelve (as he says himself), he "understood the Latin writers tolerably well, began to lisp Greek, and wrote verses with singular success." For logic, which he began to study soon afterwards, he showed as great an aptitude. In his fifteenth year he entered the University of Leipsic, where, though his principal study was law, he devoted himself to many other branches of knowledge, and especially to mathematics and philosophy. After passing a year in the study of the former science, under the celebrated Ehrhard Weigel at Jena, he returned to Leipsic, and took the degree of Bachelor in Philosophy in 1663. About this time he began to peruse with ardour the writings of Plato and Aristotle, and he used to spend entire days in a wood near Leipsic in the vain attempt to reconcile their systems. His acquaintance, however, with Greek philosophy was evinced by his metaphysical dissertation, *De Principio Individuationis*, which was read in 1664, when he graduated as Master in Philosophy. In his twentieth year, being refused at Leipsic, on account of his youth, as a candidate for a Doctor of Laws, he repaired to the University of Altorf, where he took his degree. His exercise on this occasion, which was afterwards published under the title *De Casibus in Jure Perplexis*, elicited great general applause, and procured for him the offer of a law professorship at Altorf. This he declined, and repairing to Nuremberg, chose rather to enter a society of alchemists, which he found existing there. Collecting all the current terms in books of alchemy, he wrote a letter, which, though unintelligible to himself, so favourably impressed the society, that he was forthwith introduced into their meeting, and chosen secretary. About this time the Baron de Boineburg, chancellor to the Elector of Mentz, came to Nuremberg, and was so captivated by the learning and genius of Leibnitz, that he advised him to devote himself to jurisprudence and history, and with that intent to remove to Frankfort-on-the-Maine, where he promised to obtain for him some office under the elector, his master. This advice Leibnitz followed; and the result of his studies at Frankfort appeared in his *Nova Methodus discendæ docendæque Jurisprudentiæ*, published in 1667. In 1668, at the request of Boineburg, he wrote a treatise, supporting the claims of the Prince of Neuburg to the elective throne

of Poland, which was then vacant, and sought by a crowd of candidates. This work, though elaborately written in Latin, and containing sixty propositions rigorously deduced from a series of axioms, did not attain its direct object. Neuburg was rejected; but, as a reward for his services, Leibnitz was nominated, through the influence of Boineburg, an electoral councillor. With an ever-active ingenuity, he formed a project at this period of re-casting the *Encyclopædia* of Alstedius, by rendering it more comprehensive, by introducing the articles in the order of the subjects, rather than in the order of the alphabet, and by appending to the treatise on each science a condensed account of its origin and progress, and of the authors who have treated it in detail. This design, one of the favourite ideas of the rest of his life, was never executed. In 1670, for the purpose of vindicating the works of Aristotle, he followed the unusual plan of editing a work of Nizoli against Aristotle, and expressing his own views in the preface and notes. His bold but paradoxical treatises, *Theoria Motus Abstracti*, and *Theoria Motus Concreti*, appeared in 1671. In the same year he was employed by Boineburg to write a defence of the doctrine of the Trinity against the attacks of the Pole, Wissowatius, and he produced his *Sacrosancta Trinitas per nova Argumenta logica defensa*.

In 1672 Leibnitz accompanied the son of his patron Boineburg to Paris. Here, amid distractions of every kind, he devoted his time almost exclusively to mathematics, a study in which he confessed himself to have been hitherto merely a tyro. His newly-formed intimacy with Huygens, and his eager perusal of the works of Galileo and Descartes, inspired him with ardour in his new researches; and he attempted, with great ingenuity, but with little success, to reconstruct and render perfect the arithmetical machine of Pascal. An offer made at this time, by the Academy of Sciences, to admit him into their body as a pensioner, on condition that he embraced the Romish faith, was declined.

On the death of Baron de Boineburg in 1673, being released from his duties at Paris, he visited England, and was received at once into the society of Boyle, Oldenburg, Collins, Wallis, Gregory, and Newton, and was elected a member of the Royal Society. The death of the Elector of Mentz in 1674, which left him without a patron, induced him to communicate his embarrassments to the Duke of Brunswick-Lunenbourg, who immediately tendered him the office of a councillor, with a pension and the liberty of non-residence. Leibnitz accordingly returned to Paris to prosecute his mathematical studies. After a brief sojourn, he paid a second visit to England, and repaired, by way of Holland, to the court of his new patron at Hanover, in 1676. Here he lived in a style highly congenial to his taste, employed in enriching the ducal library with valuable works and manuscripts, and receiving the full sympathy and assistance of his benefactor. About the same time, he was engaged in writing his *De Jure Suprematus et Legationis Principum Germaniæ*, and in furthering the plan of publishing the *Acta Eruditorum*, the first volume of which appeared at Leipsic in 1682.

On the death of the Duke, in 1679, his successor, Prince Ernest Augustus, afterwards George I. of England, retained the same favour for Leibnitz, and employed him to write the History of the House of Brunswick. In pursuit of materials for this task, he spent three years travelling through Franconia, Bavaria, Suabia, Austria, and Italy, searching libraries, archives, tombs, convents, charters, old manuscripts, and rare books, and amassing, in addition to the documents requisite for his History, materials available for philology, geology, and the philosophy of history. The first digest of some of these materials was his great work *Codex Juris Gentium Diplomaticus*, published in 1693, and followed by a second volume in 1700. This book, though a mere collection of manifestoes, treaties, declarations, and

Leibnitz.

Leibnitz. other public documents, is accompanied by an able preface, containing, amid many original views on the principles of natural law, his system of ethics. His accumulations supplied the matter of another work, *Accessiones Historice*, published in 1698; but not until the publication of the *Scriptores Rerum Brunsvicensium* in 1707-11, did they appear to be applied to the purpose for which they had been intended. Even this latter work was designed merely as an introduction to his History, of which he left nothing but a bare outline, published after his death in the *Acta Eruditorum* for 1717. In this outline he proposes to begin the History by a dissertation on the state of the globe, and specially of Germany, before the creation; and after an account of the manners and languages of the various tribes that successively settled in that country, to end with the real History of the House of Brunswick, including, among less important subjects, a notice of all their intermarriages and alliances with other families. His general opinions on the first of these subjects were published in his *Protogæa*, a posthumous essay, which entitles its author to be called the Founder of geology.

In 1699 he became a member of the Royal Academy of Sciences at Paris. In the following year he co-operated with the Elector of Brandenburg (afterwards Frederic I. of Prussia), in organizing a Royal Academy of Sciences at Berlin, and was rewarded for his valuable counsel with the office of President of the new institution. To the *Miscellanea Berolinensis*, which the Academy afterwards published, Leibnitz contributed many valuable papers. A correspondence which he had for a long time maintained with Bossuet touching a plan for the reunion of the Catholics and Protestants came about this time to an unsuccessful termination. He was also engaged in a vain attempt to construct a universal language; but of his long and deep meditations upon this subject, nothing remains except a few hints found among his papers after his death.

In answer to the sceptical views of Bayle on the origin of moral evil, Leibnitz, in 1710, published his most complete work, the *Theodicæe*, containing his chief opinions on metaphysics and theology, and, among others, his doctrines of pre-established harmony and optimism. So courteous and tolerant was he, in this work, towards his opponents, that several eminent men unjustly suspected him of favouring the doctrines he refuted. In 1711, Peter the Great, requesting an interview with him at Torgau, consulted him regarding the civilization of his empire, and, along with a pension, conferred upon him the dignity of a privy councillor. His latter days were embittered by his vehement controversy with Newton, touching the discovery of the differential calculus. For some time he had been grievously afflicted by fits of the gout, and having, amid his multifarious acquirements, a slight knowledge of medicine, he tried a remedy on the 14th of November 1716, which, after producing violent spasms, caused his death in less than an hour. His tomb is marked by a monument in the form of a small temple, and bearing the inscription *Ossa Leibnitii*.

Leibnitz was about the middle size, and had a spare but vigorous frame, a pleasant countenance, and keen eyes. His early-formed habit of incessant study had given him an habitual stoop, and changed his hair prematurely to gray. Invariably pursuing his studies far into the night, he sometimes denied himself the repose of his couch, and after sleeping a few hours in his chair, resumed his labours with the returning light. This abstinence he is said to have practised for several successive weeks; and some of his deep meditations kept him fixed in his chair, with scarcely an intermission, for several days together. He was equally fond of reading and contemplation. Perusing books on almost every subject, he assisted his recollection by taking short notes of their contents; but even this small aid was often unnecessary. So accurate and tenacious was his

memory, that at the age of seventy he could recite long passages from Virgil without committing a single mistake; and so well assorted was his extensive information, that George I. was wont to call him a "living dictionary." His correspondence, which comprised the most illustrious names in Europe, and extended even to China, occupied a great portion of his time. Preferring solitude to society, he was, nevertheless, as animated and eager in conversation as in study; ready and fluent in expressing his thoughts; easily irritated, but as easily appeased. Though a zealous advocate of some of the great doctrines of Christianity, he was characterized by a wide religious tolerance, which, more than the character of his recorded opinions, laid him open to the charge of a secret leaning to the Roman faith. This charge, founded on an unfinished manuscript of his, which was afterwards published under the title of *Systema Theologicum*, has been shown by Dr Guhrauer, in his life of Leibnitz, to be inconsistent with the life and previous writings of Leibnitz. Krug and Schulze have also written elaborate apologies on the subject, and the charge is now wholly abandoned. For his philosophy and opinions, see *DISSELTATIONS* I., II., and IV.

The principal sources of the biography of Leibnitz are,—his Life by Brucker, in the *Historia Critica Philosophiæ*; his Eloge by Fontenelle, in the *Hist. de l'Acad. des Sciences de Paris*, 1716; Bailly's *Eloge de M. de Leibnitz*, 1769; Kästner's *Lobschrift auf Leibnitz*, Altenb. 1769; but more especially his *Biographies* by Guhrauer, 2 vols. Breslau, 1842, and by Vogel, Leipsic, 1846. The works of Leibnitz have been singularly unfortunate in point of editing. His miscellaneous papers seem an exhaustless mine from which new treasures are continually brought to light. Four quarto volumes of posthumous works were published by Raspe in 1765; but these find no place in the *Opera Omnia*, published by Dutens in 1768. Of recent editions the most worthy of notice are those by Erdmann, Berlin, 1839-40; the *Deutsche Schriften* by Guhrauer, Berlin, 1838; *Œuvres de Leibnitz* par M. A. Jacques, Paris, 1842; and the *Gesammelte Werke*, edited by Pertz, Hanover, 1847-56, not yet completed.

LEICESTER, the chief town of the county of that name, 97 miles from London by road, and 103 by railway. It is pleasantly situate in a gentle hollow, on the bank of the River Soar. It is a very ancient town, founded, it is said, by a British king,—the King Lear of Shakspeare,—and was a Roman station, known by the name of *Ratae*. Afterwards it formed one of the five Danish burghs, or commonwealths. It was a populous city at the time of the Norman conquest. A parliament was held here in the reign of Henry V.; and Richard III., defeated and killed at Bosworth, was buried in a Franciscan convent, which then stood near St Martin's church. The town was at one time fortified, and had a strong castle; but nothing remains of the latter except the mound or earthwork of the keep. The principal streets intersect each other, and contain some good houses: indeed Leicester, as a whole, is a handsome town. The public buildings are,—the Theatre, the Assembly Rooms, the Temperance Hall, the County Lunatic Asylum, the Infirmary, the Railway Station, the Collegiate School, and the Banks, and some of them are very fine edifices. The county jail, situate at a little distance from the town, resembles a baronial castle, having portcullis and flanking towers, and turrets on the boundary walls, which inclose three acres of ground. There are nine churches, chief amongst which are St Martin and St Mary, and twenty-six dissenting chapels. Leicester is the principal manufacturing town in the county; more stockings are made here than in any other English town, with the exception of Nottingham. Yet, when stocking-knitting was first introduced, at the time of the Revolution, it was so unpopular, that it became necessary to carry it on by stealth. The other branches of industry are wool-combing and dye-

Leicester-
shire.

ing, and the manufacture of all kinds of fancy hosiery. Steam power is largely used in the town, coal being easily obtained by railway and canals communicating with the neighbouring coal-fields. Leicester contains ten parishes, and some extra-parochial places. It is divided into seven wards, and governed by a town-council, consisting of a mayor, 14 aldermen, and 42 councillors. It returns 2 members to parliament. The population was, in 1821, 31,036; 1831, 40,639; 1841, 50,853; 1851, 60,642.

LEICESTERSHIRE, an inland county of England, bounded on the N. by Nottinghamshire, N.E. by Lincolnshire, E. by Rutlandshire, S.E. by Northamptonshire, S.W. by Warwickshire, and N.W. by Derbyshire. Its name is derived from Leire, the ancient name of its chief river, the Soar. Its greatest length is, N. and S. from the junction of the counties of Lincoln and Nottingham with Leicester, to Lutterworth, 44 miles; and its greatest breadth is, E. and W. from near Rockingham to the neighbourhood of Ashby-de-la-Zouch, 40 miles. It contains 514,164 statute acres, and is the twenty-eighth of the English counties in size.

The surface of the country is a series of gentle undulations, with full and sluggish rivers winding through rich pastures intersected with hedgerows. It is a table-land, and the highest ground consists of the Charnwood Hills, in the N.W. part of the county, generally called the Forest, though now destitute of trees. It is a group of hills exhibiting sharp distinct prominences of a rugged character. The highest of them, Bardon Hill, between Ashby-de-la-Zouch and Leicester, is 852 feet above the level of the sea, and commands, perhaps, a more extensive view than any other elevation in this country: the eye ranging as far as Lincoln, 60 miles off in one direction; the Dunstable Hills, 80 miles off in another; to the Malverns in Worcestershire, the Wrekin in Salop, the Peak of Derbyshire, and the mountains of North and South Wales. This expanse comprises one-fourth of the surface of England and Wales.

The county belongs to the basin of the River Trent, which forms part of its northern boundary. It is nearly equally divided between the lias and sandstone formations; the former occupying the greater part of the eastern, and the latter the western side of the county. The coal formation exists to a considerable extent on the W., and clay-slate in the Charnwood Hills. The soil varies, but it may be described as consisting either of clay or loam, as there are very few portions of it that are calcareous, sandy, or gravelly. It is, for the most part, strong and stiff. The climate is mild.

The rivers of the county are,—the Soar, 40 miles long, rising on the S.W. edge of the county, between Hinckley and Lutterworth, and falling into the Trent, below Kegworth; the Wreak, 25 miles long, rising near Oakham, in Rutlandshire, and falling into the Soar, near Mount Sorrel; and the Anker, the Sence, the Mease, the Swift, and the Devon. These belong to the system of which the Trent is the trunk. There are, in addition, the Avon, a tributary of the Severn, and the Welland, which also passes out of the county. The Soar is navigable for 7 miles from its junction with the Trent, and this part of it, as well as a part of the Wreak, is incorporated with the system of navigation which overspreads the county. The canals are,—one from Leicester to Loughborough, 11 miles long, and rising 45 feet; one from Leicester to Melton-Mowbray, 11 miles long; one from Leicester to Foxton, 17 miles long, or, including its branch to Market-Harborough, 21 miles, having a rise of 120 feet; one from Foxton to the Grand Junction Canal, 8 miles of it being in the county; one from Melton-Mowbray to Oakham; and one from Ashby-de-la-Zouch to Nuneaton, Warwickshire. These canals, being connected with the general system of navigation, give the county access to all the great towns of the country, and to

the eastern, western, and southern sea-coasts. The railway communications consist of a line from the Ashby Canal to Moira; a line running N.W. from the River Soar, near Leicester, to Swannington, 15½ miles long, having four branches, and principally used for the conveyance of coal; the Midland Counties Railway, traversing the county from S. to N., entering the county near Lutterworth, and passing by Syston, Leicester, and Loughborough to Derby; and the Syston and Peterborough Railway, running N.E. The London and North-Western Railway also skirts the south and south-eastern boundary of the county.

Nearly two-thirds of the county are in permanent pasture, the greater part of which lies on the lias formation, while the corn land is almost entirely limited to the sandstone formation. The quantity of waste land is very small, and the open fields, from the existence of which it became a great hunting county, have nearly disappeared. The richest pasture is the low ground along the course of the rivers, and these are frequently held in conjunction with arable farms, the stock being wintered on the latter, and fattened in summer on the former. Much of the inferior grass land is employed for dairy purposes, and a large quantity of full-milk cheese is made for consumption in the N. of England. The richest cheese in the world, that called Stilton, from having been sold first in that town, is also made to a large extent in the neighbourhood of Melton-Mowbray. The mode of its manufacture was long kept a secret in a few villages; its richness arises from one quantity of milk being skimmed, and the cream taken from that being added to more milk, so that the cheese has double the usual quantity of cream in its composition. The average yield of ordinary cheese of a dairy, on moderate land, is estimated at about 3 cwts., and on better land as high as 5 cwts. for each cow. The land is much subdivided, the greater part of it forming estates of from 50 to 500 acres each, belonging to yeomen who cultivate the land themselves. The size of the dairy farms varies from 100 to 500 acres. Rent is very high, owing to the proximity of large towns, the facilities of communication which are afforded by the canals, railways, and good roads traversing the county, and the crowd of men of fortune which is attracted thither during the hunting season, a sport for which the county has long been famous, and for which it is still admirably adapted. The land, on the whole, is imperfectly cultivated, and draining and other improvements have made little progress; indeed, like most grass countries, it has slept upon its natural riches. The arable crops average from 3 to 3½ quarters of wheat, and from 2 to 4 quarters of beans per acre. The county has, however, produced an eminent farmer, Bakewell, from whose farm, Dishley Grange, near Dishley, emanated the great art of transforming breeds of domestic animals, one of the most valuable conquests of human genius. The race of sheep introduced by him—the Dishley, or New Leicester breed, as it is called,—excels all other known races for precocity, producing animals ready for fattening in one year, and full-grown in two years. Bakewell also improved the cattle of the county, and though his success was not so great as it was with sheep, he has led to the modification of every breed of horned cattle throughout the kingdom. He also improved the breed of horses, and his black horses; of the cart kind, originating principally from mares which he brought from Flanders, were the first in this part of the country to plough two horses abreast. Notwithstanding the decided superiority of the New Leicester sheep, the old breed is still reared, as well as a race of forest sheep, still more inferior. The Old Leicesters are heavy, slow to fatten, and give a coarse wool.

The mineral productions of the county are coal, freestone, limestone, coarse slate, clay for making bricks, gypsum,

Leicester-
shire.

Leicester-shire.

and a species of red granite, locally used for paving streets, and building houses. Bredon Hill is composed of a valuable kind of limestone, which forms an excellent cement, in water, and which was used in the erection of the pier at Ramsgate. There are two coal-fields, one to the N.E. of Ashby-de-la-Zouch, six or seven miles long, the other S.W., and extending 11 miles; these terminate the English coal-fields in the direction of the German Ocean. One of the beds is from 17 to 21 feet thick, and the mines are worked at an average depth of 750. Leicestershire is also a considerable manufacturing county; its productions are stockings, and all kinds of fleecy hosiery, bobbin-net lace, felt-hats, and carpets. Six-tenths of the stockings are of the coarse kinds, and it is estimated that 20,000 knitting-frames, and 35,000 persons are employed in this branch of manufacture. A large number are also occupied in wool-combing, and in spinning woollen and cotton yarn. Leicester, Loughborough, and Hinckley are the chief localities of manufacturing, but it is carried on very generally throughout the towns and villages of the county.

Leicestershire was anciently part of the territory of the Coritani, and was afterwards included in the Roman province of Flavia Cæsariensis. It contained several Roman stations, but the only traces of them remaining are those of *Rata* (Leicester). Under the Saxons the county was incorporated with the kingdom of Mercia. In the seventh or eighth century it was the seat of a bishopric, which in the ninth was united with the see of Lincoln. In 878, in accordance with a treaty between Gothrun the Dane, and Alfred the Great, the county became part of the Danish territory; but in the reign of Edward the Elder, it was conquered by the Saxons, and restored to the kingdom of Mercia. William the Conqueror divided the county amongst his relations and friends, and they built castles upon their possessions; but these edifices have perished, all that remains of them being a few fragments of Ashby and Groby Castles. Belvoir Castle was destroyed by Lord Hastings, in the wars of the Roses. The present edifice, the noble residence of the Dukes of Rutland, is of modern date. Leicester Castle was captured by William Rufus, in the struggle with Robert Duke of Normandy. The county was a battle-field in the contests of John and Henry III.; and in 1485, the war of the Roses ceased in the defeat and death of Richard III. at the battle of Bosworth Field, near Market-Bosworth. A tablet has lately been set in the gable of a new building at Bowbridge, Leicester, commemorating the fact that the "crooked-backed tyrant" lies buried near the spot. The county was again much disturbed in the civil war between Charles I. and the Parliament. Leicester was captured by the king in 1645, and the decisive battle, which led to his dethronement and execution was fought a fortnight afterwards, on the borders of the county at Naseby, Northamptonshire.

The antiquities of the county are a tumulus at Radcliffe on the Wreak, 350 feet long, and 120 broad, attributed to the Celts; a remarkable parallel embankment near Leicester, locally called the Raw Dykes, and supposed to be the bounds of a British race-course; traces of the Roman roads, the Watling Street, the Via Devena, and the Fosseway; a Roman wall, called the Jewry Wall, at Leicester, built of alternate courses of ragstone and brick, and having several arches turned with tiles; tessellated pavements at Rothley and Wanlip; and remains of encampments, supposed to be Roman. Coins of the Roman emperors Titus, Trajan, Diocletian, Constantine, Constantius, Hadrian, and others, have been found at different times and places. The Gothic remains are those of the Abbey of Leicester, of the Nunnery of Grace Dieu, Ulvestoft Priory, Laund Priory, the castle of Ashby-de-la-Zouch, the churches of Hinckley and Melton-Mowbray, and the chapel of Market-Harborough.

VOL. XIII.

The pulpit and part of the vestments of the great reformer Wickliffe are still preserved in the church of Lutterworth, of which he was the pastor. He was buried there in the year 1387; but in 1428, by order of the Council of Sienna, his bones were taken up and burnt, and the ashes thrown into the river. Thus, to use the words of Fuller, "the Swift conveyed them to the Avon, the Avon into the Severn, the Severn into the narrow seas, and they into the wide ocean," foreshadowing the dispersion of the Bible, which he first translated into English, over the whole world.

The county is divided into 6 hundreds and 206 parishes. The population was, in 1821, 174,571; 1831, 197,000; 1841, 220,304; 1851, 234,938.

The chief towns are,—

	Population.		Population.
Ashby-de-la-Zouch	3,762	Lutterworth	2,446
Castle Donnington	2,729	Melton-Mowbray	4,391
Hinckley	6,111	Market-Harborough	2,325
Loughborough	10,900	Leicester	60,584

The amount assessed to the property and income tax within the county in 1851 was L.1,364,270.

The number of places of worship in the county in 1851 was 650, viz.,—Church of England, 289; other denominations, 361. The total attendance at the services in the morning, afternoon, and evening was,—Church of England, 157,982; other denominations, 147,802.

The number of day schools was 709, with 28,257 scholars, viz.,—Public schools, 278, with 19,392 scholars; private schools, 431, with 8862 scholars. Sunday schools, 432, with 36,280 scholars, viz.,—Church of England, 227 schools, 17,217 scholars; other denominations, 205 schools, 19,063 scholars. (F. C.)

LEIGH, EDWARD, a learned theological critic, was born at Shawell in Leicestershire, in 1602. After studying at Oxford, where he enrolled as a commoner of Magdalen Hall in 1616, he became a student of law in the Middle Temple. He then devoted himself to his professional duties and literature till 1636, when he entered parliament as member for Stafford. He became a colonel in the parliamentary army during the civil war, and soon afterwards a member of the Assembly of Divines. Being favourable to a reconciliation with the king, he was turned out of parliament along with the Presbyterian party in 1648. From this time, till his death in 1671, he was engaged in the study of theology, and published the following works:—*A Body of Divinity*, London, 1654; *Annotations on the Five Poetical Books of the Old Testament*, London, 1657; *Annotations upon all the New Testament*, London, 1650; *A Treatise of the Divine Promises*, London, 1633; *Critica Sacra*, his most important work, London, 1662; *A Treatise of Religion and Learning, and of Religious and Learned Men*, London, 1656.

LEIGH, a manufacturing and market-town of England, county of Lancaster, on the Wigan Canal, 12 miles W. of Manchester. It consists of two principal streets, from which several smaller ones diverge in different directions. The only public buildings are, an old parish church, the town-hall, and several chapels. The inhabitants are chiefly employed in the manufacture of cotton, silk goods, cambrics, muslins, and fustian, especially the two first. In the neighbourhood cheese and glue are made to some extent. The factories are plentifully supplied with coal and lime from the surrounding country, which abounds with these minerals. Market-day, Saturday. Two annual fairs are held here, where cattle and cheese form the staples of trade. Leigh has railway and canal communication with all the manufacturing and mining districts of Lancashire. Pop. (1851) 5206.

LEIGHTON, ROBERT, Archbishop of Glasgow, was born in the year 1611. His father, Alexander Leighton,

Leigh,
Edward
Leighton.

Leighton.

a descendant of the ancient family of Ulyshaven in Forfarshire, commenced his academical studies at St Andrews, and afterwards repaired to Leyden, where he took the degree of M.D. Having fixed his residence as a medical practitioner in London, he met with strong opposition from the College of Physicians. In order to publish his *Sions Plea against the Prelacie*, he retired to Holland; and in 1629 became minister of the English church at Utrecht. But his conscientious scruples in regard to the observance of festivals, induced him to resign his charge within a few months. His book having been printed in the course of the preceding year, he returned to London. Two copies were presented to parliament two days before the dissolution; and he was immediately arrested by two pursuivants of the high commission, and conducted to the house of Laud, then Bishop of London, and inquisitor-general of England. On the bishop's warrant he was committed to a loathsome dungeon in Newgate, and only after fifteen weeks did the inquisitors permit his wife to visit him. In the interval his house had been ransacked and robbed by Laud's emissaries, who by their brutality so frightened one little boy of five years old, "that he never recovered it all his days." By flattering promises, one of Laud's agents prevailed upon him to confess that he was the writer of the book; but neither threats nor entreaties could induce him to betray any one of his friends and adherents. Before the court of Star-Chamber he repeated the admission, that he was the author of the book, but denied all criminality of intention. No counsel dared to plead his cause, and he returned to prison to await his doom. It was the opinion of four physicians that poison had been administered to him in Newgate. He had been seized with a violent distemper, which was accompanied with loathsome symptoms, and his strength was so completely exhausted that he could not be produced before this atrocious court. In his absence, he was sentenced (4th June 1630) to pay a fine of £10,000; it was also ordained that the high commission should degrade him from his ministry; that he should be brought to the pillory at Westminster, should be whipped, have one of his ears cut off, one side of his nose slit, and his face branded with the letters S. S., denoting a sower of sedition; that he should then be carried back to prison, and, after a few days, should again be pilloried at Cheapside, should then likewise be whipped, have his other ear cut off, and the other side of his nose slit; and should then be detained in close custody in the Fleet prison for the remainder of his life. When this sentence was pronounced, it has been stated that Laud pulled off his cap, and gave thanks to the God of mercy.¹ Before the execution of the sentence, Leighton made his escape from prison; and two of his countrymen, named Anderson and Elphinstone, were each fined £500 for aiding and abetting him in his flight. He was, however, retaken in Bedfordshire, and endured the first part of his punishment on the 26th of November; it was inflicted with the most unrelenting severity; the second part followed after a short interval; and thus miserably mutilated, he lingered in prison for nearly ten years.² In 1640 he presented a petition to the Long Parliament, reciting the direful persecution to which he had been subjected, and he now obtained such redress as could be afforded to him; "but," as Dr Benson has too truly re-

remarked, "no sufficient reparation in this world could possibly be made to a man so highly injured."³

Leighton.

ROBERT LEIGHTON, the eldest son of this learned and persecuted individual, is commonly represented as a native of Edinburgh; but as Burnet speaks of his father having sent him to be educated in Scotland, it has been inferred that he was born in London.⁴ He entered the University of Edinburgh in 1627; and, though even at that time remarkable for his piety, was censured for writing an epigram on the provost of the city. He made uncommon progress in his studies, and took the degree of A.M. in 1631. After he left the university he travelled on the Continent, and, among other places, visited Douay, where some of his relations were then residing. In France he spent several years. Returning to the land of his fathers, he became, on the 16th December 1641, Presbyterian minister of Newbattle, a parish within 7 miles of Edinburgh. He had now attained the age of thirty, and was qualified by his natural endowments, as well as by his acquired knowledge, to appear with singular advantage in his public capacity. His large and tolerant views, however, made him withdraw from the society of his brethren, and his retiring disposition caused himself seldom to let his voice be heard beyond the precincts of his parish. Bishop Burnet, who speaks with enthusiasm of Leighton's style of preaching, tells us that he had "a very low voice, and could not be heard by a crowd."

In 1648 Leighton declared in favour of the Engagement for the king, and thus exposed himself to the hazard of being subjected to heavy penalties. When some of his parishioners, who had been concerned in the unfortunate expedition to England, were enjoined to make a public profession of their repentance, he studiously avoided all mention of the grounds of the war, but admonished them that "they had been in an expedition in which, he believed, they had neglected their duty to God, and had been guilty of injustice and violence, of drunkenness, and other immoralities, and he charged them to repent of these very seriously." The Earl of Lothian, who resided in his parish, and entertained a high esteem for his character, had sufficient influence to protect him from any serious annoyance. It is, however, evident that he found himself placed in a very uncomfortable situation: and his uneasiness must in no small degree have been increased by the differences which unhappily ensued between the Resolutioners and Protesters. He was at length induced to resign the pastoral charge of Newbattle in 1652.

On the 17th January 1653, Leighton was elected principal of the University of Edinburgh, and was persuaded to accept an office for which he was so eminently qualified by his character, his talents, and his attainments. Being *ex officio* primarius professor of divinity, he often preached to the students in Latin, with such animation and purity of style as to draw crowded audiences. His conversation and piety had an equally good effect upon the youth under his charge. He also increased the temporal prosperity of the university, by soliciting and obtaining from Cromwell an annuity of £200 to increase its funds, which were then very low.

During the vacations, he made occasional excursions to England, and even to Flanders. He had an opportunity of observing the character of the eminent men who fre-

¹ Even in the solitude of his prison, Laud seems to have entertained a deliberate opinion that Dr Leighton's punishment had fallen short of his deserts. "In which book of his," he remarks very coolly, "were many things, which in some times might have cost him dearer" (*Hist. of the Troubles and Tryal of Laud*, vol. i., p. 198).

Leighton. quented the Protector's court; but in his continental tours found more congenial society in the Jansenist divines, who seemed to be struggling for that primitive simplicity on which his own heart was set. At his restoration Charles II. tried to force Episcopacy upon Scotland, as he considered that form of church government most favourable to his despotic opinions. The politic apostate Sharp, the willing tool of the king, was appointed Archbishop of St Andrews and Primate of Scotland; and, chiefly at his recommendation, three bishops were nominated. One remained to be chosen, and Leighton was pointed out as a proper person. His brother, Sir Elisha Leighton, who had embraced Popery, and become secretary to the Duke of York, commended him to Lord Aubigny, and on account of his celibacy and ascetic mode of life, falsely represented him as fostering a secret favour for the Romish faith. At this nobleman's suggestion, Charles appointed Leighton one of the five bishops. Leighton, who was then in London, on his return from Bath, where he had been residing for the benefit of his health, was persuaded, after considerable difficulty, to accept of the bishopric of Dunblane, a small diocese, as well as a small revenue. He had previously cultivated an acquaintance with several Episcopalians, and, among others, with the father of Bishop Burnet. No person of ordinary candour can impute his change to any unworthy motive. Considering church government as a matter not determined by any positive injunctions, but open to the adjustment of bodies of men varying in their opinions, and placed in a variety of circumstances, he also cherished the hope (as he himself says) "of reconciling the devout on different sides."

Of the four bishops-elect, only two had received episcopal ordination; but before the consecration of the other two, Sharp and Leighton, it was considered as absolutely necessary to ordain them deacons and priests, since they could not be considered as really presbyters: an opinion which was by no means prevalent previous to the ascendancy of Laud, and which has since been ably refuted by Bishop Stillingfleet. To this idle ceremony of re-ordination, Sharp, who had "swallowed down greater matters," submitted with no small reluctance, but Leighton had good sense enough to know that it was a matter of no consequence whether he submitted to it or not. These two were privately ordained deacons and priests; and on the 15th of December 1661, all the four were publicly consecrated in Westminster Abbey. The good Bishop of Dunblane was scandalized at the feasting and jollity which followed this religious ceremony. They travelled towards Scotland in one coach; and Leighton stated to Burnet that he believed his associates were weary of him, for he was very weary of them. When he found that they intended to enter the metropolis with some degree of pomp, he left them at Morpeth, and saved himself from a triumphal entry by reaching Edinburgh a few days before them. When parliament assembled in the month of April 1662, most of the bishops took their seats, but Leighton did not appear among them; and he still retained enough of presbytery to refuse the title of *Lord*. With his new associates Leighton could mingle far less than with the intolerant presbytery of Newbattle; and as they carried their relentless schemes into his diocese, he quickly lost heart and hope. In 1665 he announced to the clergy of Dunblane his intention of resigning; and with a tale of sorrow, which moved even the heart of the king, he supplicated for leave to retire from his bishopric. The king, however, persuaded him to retain his office, promised the adoption of a more lenient policy, and suspended the functions of the ecclesiastical commission. But most of his Scottish ministers were so destitute of principle and humanity, that no material improvements ensued. The Presbyterians were subjected to intolerable grievances;

and at length, in 1666, had recourse to arms, when their military proceedings were very speedily terminated at the battle of Pentland Hills.

In the midst of these scenes of persecution, the gentle spirit of Leighton must have been heavily afflicted. He opposed all the violent methods of producing a formal compliance with the established mode of worship, and made great exertions to secure a general and permanent toleration. With this view he repaired to court in 1669, and had two audiences of the king. One of those who seconded his endeavours was Dr Wilkins, Bishop of Chester. The proclamation of indulgences complicated the politics of both parties, and for his zeal against the measure, Dr Alexander Burnet, Archbishop of Glasgow, found it expedient to retire to a private station, with the provision of an annual pension. It was not without much reluctance that Leighton was induced to accept of the vacant office; and, as his translation was attended with some informalities, he became, according to the strictness of ecclesiastical law, not archbishop, but administrator of the bishopric.¹ He removed to Glasgow in 1670, and in the course of the preceding year his friend Dr Gilbert Burnet had been elected professor of divinity in that university. They appear to have lived upon terms of great cordiality; and to Burnet, who became Bishop of Salisbury, we are indebted for a copious and most interesting record of his evangelical virtues.

Soon after his translation, he held a synod of his clergy, who uttered many complaints of being deserted by the people; but Leighton only exhorted them to lay aside all desire for revenge and to humble themselves before God. "This was a new strain to the clergy. So they went home, as little edified with their new bishop as he was with them." Accompanied by the professor of divinity, he afterwards visited some of the most eminent of the indulged ministers in different districts, with the view of persuading them to listen to terms of accommodation. In the presence of the Earls of Lauderdale, Rothes, Tweeddale, and Kincardine, he held a conference at Edinburgh with six of the Presbyterian clergy; but his arguments in favour of Episcopacy produced no effect upon those to whom they were addressed, and a second conference was attended with the same result. Leighton tried also to obtain some mitigation of the acts against conventicles. In reference to one of them, he declared to the Earl of Tweeddale, that the entire tenor of it was so contrary to the common rules of humanity, not to say Christianity, that he was ashamed to participate in the councils of those who could frame and pass such laws. Nor must it be forgotten that these atrocious laws were not suffered to continue a dead letter.

In the course of one year, four bishoprics became vacant, and the choice of them was offered to Dr Burnet. Leighton was authorized to recommend such individuals as he thought most worthy of promotion; but as neither Burnet, Charteris, nor Nairne, could be induced to undertake the office, he found himself beset with new discouragements. Having failed in his endeavours to conciliate the Presbyterians, being suspected and hated by the Episcopalians, and in utter despair of securing any benefit to others or satisfaction to himself, he repaired to London in 1672, and, not without considerable difficulty, obtained the king's permission to resign his preferment, after an interval of one year. He, however, retained it till the year 1674, and Alexander Burnet was then restored to his former dignity. After residing for some time within the precincts of the University of Edinburgh, Leighton retired to England, and spent the remainder of his life with his sister Sapphira, the wife, and finally the widow, of Mr Lightwater of Broadhurst, a demeane in the parish of Horsted Keynes, and county of Sussex. His time was chiefly spent in devout seclusion,

Leighton-
Buzzard.

but he frequently officiated in the parish church, and in some others of that vicinity. In the year 1679, at the suggestion of the Duke of Monmouth, the king was induced to request that he would again fix his residence in Scotland, and use his endeavours in reconciling the ecclesiastical animosities which still prevailed in that country. But the Duke soon afterwards ceased to have any influence in the affairs of either kingdom, and this negotiation seems to have made no further progress.

In 1684 Leighton was urged by Dr Burnet to make a journey to London, for the purpose of meeting the Earl of Perth, Chancellor of Scotland, who had expressed an earnest wish to see him. When he reached the metropolis, Burnet was surprised to see him look so fresh and active at his advanced period of life: his hair was still black, and he retained much of his former vivacity, with the same quickness of conception and strength of memory. He, however, spoke of his work and journey being nearly finished at the same time; he was next day seized with a pleurisy; on the following day he suddenly fell into a state of insensibility, which continued for about twelve hours, when he expired, June 25, 1684, at an inn in Warwick Lane, in the seventy-fourth year of his age, ten years after he had ceased to be Archbishop of Glasgow. His remains were deposited at Horsted Keynes. A great portion of his income had been devoted to deeds of charity and benevolence; and by a will, dated on the 17th of February, he had destined the residue of his property to charitable uses. To his sister, and to her son, Edward Lightwater of Broadhurst, he only left a small token of grateful acknowledgement of the great kindness with which they had treated him while he was their guest. His library he bequeathed to the Cathedral of Dunblane, where it is still preserved.

The grave learning, piety, and charity of Leighton has been described by Bishop Burnet in very striking colours. His gentle nature was never ruffled with bursts of angry passion; and in those troublous times his loving spirit was never known to gratify itself in laughter, and very seldom was he even seen to smile. Of his indifference to fame we have a sufficient proof in the fact of his never having committed any of his works to the press.

The following is a list of his writings:—*Sermons*, Lond. 1692, 8vo; *Praelectiones Theologicae*, Lond. 1693, 4to. Of a very recent date, there is a more correct edition, published under the title of *Roberti Leighton, S. T. P. Archiepiscopi Glasguensis, Praelectiones Theologicae; Parmenses; et Meditationes in Psalmos* &c., *avarii, cæcæ, ethico-criticae. Editio nova, recensente Jacobo Scholefield, A.M. R.S.L.S. Græcarum Literarum apud Cantabrigienses Professore Regio, et Collegii SS. Trinitatis nuper Socio*, Cantabrigiæ, 1828, 8vo. An English translation of the prelections and exhortations had been published with the title of *Theological Lectures*, Lond. 1763, 8vo; *A Practical Commentary upon the First Epistle General of St Peter*, York and Lond. 1693-4, 2 vols. 4to; *An Exposition of the Creed, Lord's Prayer, and Ten Commandments; with two Discourses, on St Matth. xxii. 37, 38, 39, and Heb. viii. 10; to which is annexed a short Catechism*, Lond. 1701, 8vo; *Tracts, including Rules for a Holy Life, a Sermon, and a Catechism*, Lond. 1708, 12mo. After a considerable interval appeared *Select Works of Archbishop Leighton, some of which were never before printed; to which is prefixed an Account of the Author's Life and Character*, Edinb. 1746, 8vo. This publication was soon followed by *The Expository Works and other Remains of Archbishop Leighton, some of which were never before printed; revised by P. Doddridge, D.D., with a preface*, Edinb. 1748, 2 vols. 8vo. There are many other editions of a subsequent date, but among these we shall only specify that of Lond. 1825, 4 vols. 8vo, which has been reprinted several times, and contains a life of the author by the Rev. John Norman Pearson.

LEIGHTON-BUZZARD, a market-town of England, Bedfordshire, on the Grand Junction Canal, 40 miles N.W. of London by railway. Its streets are ill laid out, and the sewerage is defective. An elegant pentagonal cross, two storeys in height, and said to have been erected in the fourteenth century, stands in the market-place. The parish church, built in the early part of the thirteenth century,

has been so frequently repaired that it has in a great measure lost its original appearance of early English architecture. There are, besides, in the town a new town-hall, a literary institute, and several chapels, schools, and charities. The trade is partly dependent on straw-plaiting and lace-making, executed by the women; and partly on the cattle, horses, timber, and wool of the neighbourhood. Cattle are reared here in large numbers for London consumption. Market-day, Tuesday, chiefly for cattle; and five fairs take place during the year, the July one for wool exclusively. Pop. (1851) 4465.

LEINE, a river of N.W. Germany, rises in Eichsfeld, flows N. by W. through Prussian, Brunswick, and Hanoverian territories, receives on its right the Ruhme and Innerste, on its left the Kaspau, and joins the Aller (a tributary of the Weser) on the left, near Hudemühlen, after a course of about 130 miles. The chief town on its banks is Hanover, where the river becomes navigable.

LEINSTER, the most eastern province of Ireland, bounded by Ulster on the N.; by St George's, or the Irish Channel, on the E. and S.; and by the provinces of Connaught and Munster on the W. The capital city of this province and of the kingdom is Dublin. It contains twelve counties, viz., Carlow, Dublin, Kildare, Kilkenny, King's County, Longford, Louth, Meath, Queen's County, West Meath, Wexford, and Wicklow. It comprises an area of 4,876,211 acres, being, therefore, with the exception of Connaught, the smallest province of Ireland. The general elevation of its surface is also less than that of the other provinces, excepting Connaught.

LEIPSIC, or more correctly LEIPZIG, one of the four circles into which Saxony is divided, comprises the N.W. part of that kingdom, and is bounded on the N. and W. by Prussia, S. by Saxe-Altenburg and the circle of Zwickau, and E. by the circle of Dresden. Area, 1336 square miles. The country is generally level, and lies lower than any other part of Saxony. It is most elevated in the S., where some offsets of the Erzgebirge appear, but do not attain any great height. Leipsic belongs to the basin of the Elbe, and is principally drained by its tributaries the Elster and Mulda. The soil is fertile, and in general well cultivated. The principal crop is corn. The rearing of cattle, and especially of sheep of a superior breed, is much attended to. Tobacco is extensively grown. There are no metals; but limestone, marble, potters' clay, fullers' earth, and peat are abundant in various parts. The manufactures in this circle are flourishing, and include woollen, cotton, and linen goods, and earthenware. Pop. (1855) 454,262.

LEIPSIC, or *Leipzig*, the capital of the above circle, and the second city in the kingdom, is situate in an extensive and fertile plain, on the White Elster, here joined by the Pleisse and Parde, 72 miles W.N.W. of Dresden by railway. The fortifications which formerly surrounded the town have been converted into beautiful walks and gardens. The houses are chiefly old-fashioned stately buildings, frequently six storeys in height, besides three or four additional ones in the pyramidal roof, and exhibiting much carved masonry. The streets are narrow, and from the height of the houses, have rather a dingy appearance, but are well paved and clean. The suburbs, however, of which there are four, are of recent date, and more regularly built. In the centre of the town is the great market-place or square, which has a very picturesque appearance from the quaint architecture of buildings which surround it. One of these is the town-house, built in 1556, where the allied sovereigns met to congratulate each other after the battle of Leipsic. Here, too, is the *Königshaus*, formerly a residence of the electors and kings of Saxony, and occupied by Napoleon during the battle of Leipsic. Near this is Auerbach's Cellar,

Leine
||
Leipsic.

Leiria. a spirit-vault said to have been frequented by Dr Faust, and here Goethe has laid a scene of his celebrated tragedy. The poet, not less than his hero, is said to have frequented this place when a student. The old castle of Pleissenburg, which, during the Thirty Years' War, withstood the attacks of Tilly for several weeks after the town had surrendered, stands in the S.E. part of the town. The lower part of it is now used as a wool warehouse, and the tower as an observatory. Several of the churches are handsome buildings, as those of St Nicholas, St Thomas, and St Paul. Among the other public buildings are the university, cloth hall, booksellers' exchange, post-office, and theatre. The University of Leipsic, founded in 1409, is one of the first in Germany. In 1853-4 it had 113 professors and teachers, and 807 students. Besides faculties of theology, law, medicine, and philosophy, it has a library of 150,000 volumes, and 2000 MSS., an anatomical theatre, clinical institution, botanical garden, observatory, chemical laboratory, museums, &c. The *Augusteum*, a very elegant building connected with the university, was erected in 1836, and named after King Frederick Augustus. It is three storeys in height, and contains the library, lecture-rooms, &c. In the *Paulinum*, another elegant building, are the museums of natural history and anatomy. This university is rich in endowments for stipends to scholars. Leipsic is well supplied with other educational and literary institutions. It is connected by railways with Dresden, Magdeburg, Berlin, and Altenburg, and is the centre of a very extensive trade. The celebrated Leipsic fairs are held here thrice a year,—on the 1st of January, at Easter, and at Michaelmas. They usually last for three weeks, and are attended by merchants from all parts of Germany, England, France, America, Russia, Italy, Greece, Turkey, Persia, &c. The goods comprise all kinds of woollen, linen, and cotton stuffs, silks, lace, hardware, jewellery, watches, toys, paper, books, leather, &c. The value of the goods brought to these fairs in 1855 was estimated at about £11,000,000 sterling. On these occasions the town presents the greatest bustle and confusion—the streets and squares are occupied by temporary booths in addition to the ordinary shops, while the population of the town is nearly doubled. The Easter and Michaelmas fairs, particularly the former, are famous for the vast number of new publications brought there for sale. The Easter fair is attended by booksellers from all parts of Germany, and even from other countries, sometimes to the number of 600. Prospectuses and specimens of new publications are brought here for circulation, annual accounts are settled, and purchases made. In the Easter fair catalogue for 1856 the number of new works announced as published in Germany during the preceding year was 9540, as forthcoming 1171. Leipsic is also of considerable importance as a manufacturing town. It has large type-foundries, oil-mills, paper-mills, and manufactories of silken goods, stockings, leather, hats, hardware, musical, optical, and mathematical instruments. There are about 150 publishing establishments in the town; and in 1853 there were 36 printing offices, with 58 steam, and 164 hand presses. Leipsic was the scene of a tremendous conflict on the 16th, 17th, and 18th of October 1813, between the allies under Prince Schwartzenberg, and the French under Napoleon, in which the latter were totally defeated. See HISTORY OF FRANCE. Pop. (1855) 69,986.

LEIRIA, a town of Portugal, capital of a cognominal administration, in Estremadura, is situate in a fertile valley on the right bank of the Liz, at its junction with the Lena, 75 miles N. by E. of Lisbon, and 15 miles from the Atlantic. An old castle, founded in the twelfth century, occupies a commanding position on a rock in the centre of the town. Leiria is the see of a bishop, and contains a cathedral of comparatively modern date, several churches and convents, besides a college, an hospital, and small

theatre. The chief articles of trade are glass and fine timber, the former being manufactured largely in the adjacent village of Marinha, while the latter is brought from the extensive forests in the neighbourhood. There are some warm and medicinal springs near the town. At Leiria, in 1466, the first printing-press in the Peninsula was set in motion. The poet Rodriguez Lobo was born here about the middle of the sixteenth century. In July 1808, the town was seized by the French under General Margarot, after a feeble resistance, and many atrocities committed. Pop. about 3000.

LEITH, although an independent burgh, may be considered the seaport of Edinburgh, from which it is only about a mile and a half distant. The Water of Leith, at its confluence with the Firth of Forth, divides the town into two parts, called respectively, North and South Leith. The first mention made of Leith is in the charter of erection of Holyrood Abbey, founded by David I. in 1128, where it is styled Inverleith. The magistrates of Edinburgh obtained a grant of the harbour and mills from Robert I. in 1329, and they subsequently purchased, from Logan of Restalrig, all the other rights and privileges. Its municipal government and admiralty jurisdiction continued in their hands until the year 1833, when the Burgh Reform Act conferred on Leith the right of electing its own magistrates, and the management of its own municipal affairs.

From the earliest times down to a recent period there existed a petty rivalry between the inhabitants of Leith and Edinburgh, an evidence of which was given so early as the year 1485, when the magistrates of Edinburgh, to prevent the citizens of Leith competing with them in trade, passed an act ordaining that no merchant of Edinburgh should presume to take into partnership an inhabitant of Leith under the penalty of 40 shillings Scots, and the loss of the freedom of the city. The civil and political history of Leith is thus so united with that of the metropolis that most of the leading events are described in the account of the latter. Its importance as the principal channel for the admission of troops and supplies made the possession of it an object with the conflicting parties during the turbulent period of the Reformation, and the subsequent contests for ascendancy between the supporters and enemies of the Stuart family.

As Edinburgh was the stronghold of the Protestant party, Leith was that of the Roman Catholic party, who, headed by Mary of Guise, then Regent of Scotland, and assisted by a body of French soldiers, sustained within it, in the year 1560, a siege of two months.

The modern streets of Leith are spacious and well built, but the older ones are irregular and contracted. The principal buildings are the Exchange, the Custom-house, the Town-house, the church of South Leith (one of the few ancient Gothic buildings now used in Scotland for public worship), and the Forts, one of the military stations of the United Kingdom for a small body of artillery.

The chief manufactures of Leith are ropes, sailcloth, locomotive engines and machinery, glass, soap, ale, refined sugar, and oil seed cakes. Iron and timber ship-building is also carried on to a considerable extent.

Various efforts have from time to time been made to overcome the natural obstacles that lay in the way of Leith as a shipping port. In 1720 a dock was formed on the E. side of the river, and in 1777 a small quay called the Custom-house quay was built. Between 1800 and 1817, two wet docks were constructed, each measuring 750 feet in length by 300 in width, and having a united area of about 10 acres. In 1831 two great additional works were undertaken, viz., an addition to the old or E. pier of 500 yards, and the formation of a covering bulwark, by means of which the water in the channel was deepened about two feet. There were still, however, only 17 feet of water over the bar at its mouth at high-water spring tides, and no vessel

Leith.

Leith. of above 400 tons could enter the harbour without lightening. Farther improvements were commenced in 1848, and completed in 1855. These included the formation of the Victoria Dock, equal in extent to either of the others; the new western pier and low-water landing slip; the extension of the eastern pier 1000 feet seaward. The length of the E. pier is now 3530 feet, and of the W. 3123 feet. They are unsurpassed by any in the kingdom; and, in addition to other important purposes, afford the means of a healthful and pleasant promenade. By means of these improvements, a depth of 26 feet water has been obtained in the new harbour at high-water spring, and of 21 feet at neap, tides. The Victoria Dock has 25 feet water at spring, and 20 feet at neap, tides, upon the gate sill, and two feet more within the dock; and the two old docks have 18 feet at spring, and 13 feet at neap, tides. Vessels of upwards of 2000 tons burden, of 320 feet in length and 58 feet in breadth, can be accommodated in the Victoria Dock.

There are also five dry or graving docks at Leith, of the following dimensions:—

No. of Docks.	Length		Width			Depth of water over dock sills at high-water spring tides.
	O	At top.	Of floor.	At top.	Of gates.	
	ft. in.	ft. in.	ft. in.	ft. in.	ft. in.	
2	160 0	174 0	45 0	70 6	36 0	16 6
1	173 0	177 0	32 0	58 0	36 0	13 8
1	166 0	172 0	36 9	49 6	30 9	12 5
1	117 6	121 6	41 0	51 0	33 9	12 6

A new graving dock of greater capacity is proposed to be made on the E. sands, and to enter the present new harbour a little to the N. of the entrance to Victoria Dock. The following are its proposed dimensions. Length of floor 300 feet, at top 330 feet; width of floor 45 feet, at top, 80 feet; of caisson, 72 feet; depth of water over sills at high-water springs, 24 feet 5 inches.

Besides having regular steam communication with Rotterdam, Hamburg, Hull, London, Newcastle, and the north of Scotland, Leith trades largely with the Baltic, Mediterranean, North America, and Australia. The exports are principally coal, iron, spirits, ale, paper, linen yarn, &c. Of coal and iron the quantities exported during the last three years were as follows:—

EXPORTS.			
DATES.		Coals.	Pig-iron.
		Tons.	Tons.
15th May 1853 to 15th May 1854		29,773	24,072

The amount of customs duties received at Leith for the last four years were,—1853, L.485,915; 1854, L.455,403; 1855, L.462,917; and 1856, L.498,172. The vessels registered as belonging to the port on 31st December 1855, were,—sailing vessels, of and under 50 tons, 71; tonnage, 2218: above 50 tons, 80; tonnage, 17,058;—steam vessels, of and under 50 tons, 14; tonnage, 289: above 50 tons, 23;

tonnage, 6654. The recent war with Russia has checked the increase in the trade that would otherwise have resulted from the greatly enlarged accommodation.

Leith is governed by a provost, 4 bailies, and 10 councillors; and unites with Portobello and Musselburgh in returning a member to Parliament. Pop. (1851) 30,919; constituency, 1375.

¹ The increase would have been much greater had not most of the Leith steamers being employed as transports. Since the peace the increase has been very decided. During the seven months ending 31st December 1856, 565 steam vessels, of 81,090 tons, entered; and 558, of 78,727 tons, left the port.

Leitmeritz
||
Leitrim.

LEITMERITZ, a town of Austria, capital of a cognominal circle in Bohemia, on the right bank of the Elbe, here crossed by a long bridge, and on the Prague and Dresden Railway, 48 miles N. by W. of the former, and 69 S. by E. of the latter. It is the see of a bishop, and contains a cathedral of the eleventh century, a town-house, hospital, a college, and a theological school. Coach-building, and the making of straw hats and musical instruments, are carried on. It has also a brisk trade in the wine and grain of its fertile neighbourhood. Pop. 7100.

LEITRIM, a county of the province of Connaught, in Ireland, bounded N. by the bay and the county of Donegal, E. by the counties of Fermanagh and Cavan, S. by those of Longford and Roscommon, and W. by Roscommon and Sligo. Its only claim to be considered a maritime county is the possession of 3 miles of coast on the Bay of Donegal. In shape it has been compared to an hour-glass, broad at both ends, and contracted in the centre. Its greatest length, measured from S.E. to N.W., is 52 miles; its breadth where broadest is 20, and where narrowest not more than 7 miles; extending over an area of 613 square miles, or 392,363 acres, of which 249,350 are arable, 115,869 uncultivated, 3396 in plantations, and 23,748 are under water. Of the 116,000 acres of uncultivated land, 55,500 are coarse pasture above 800 feet over sea level, 60,500 coarse pasture below 800 feet, including flow bogs, &c.; 30,000 are improveable for cultivation, 36,000 improveable for pasture, and 50,000 acres are incapable of improvement.

The county, which derives its name from an ancient but now obscure village on the Shannon, is supposed to have formed part of the region inhabited by the tribe of the Nagnatæ in the time of Ptolemy. The Irish chroniclers distinguish it by the name of Hy-Brune-Brefine, or Brennie. The family of O'Rourk, which derived its descent from Roderic, King of Ireland, held in it the rank of chieftains; and under them were the O'Murreys, M'Loughlins, M'Glanchies, and M'Granells. It was made shire-ground, together with the other counties in Connaught, during the reign of Queen Elizabeth; and is now divided into the five baronies of Carrigallen, Dromahaire, Leitrim, Mohill, and Rosclogher. These baronies are subdivided into seventeen parishes, of which ten are in the diocese of Kilmore, and seven in that of Ardagh. The county is in the Connaught circuit, and the assizes are held at Carrick-on-Shannon, which is the station of the county inspector of constabulary. For poor-law purposes, Leitrim is divided into the unions of Manor-Hamilton, Mohill, and Carrick-on-Shannon, and small portions are included in the neighbouring unions of Bawnboy and Ballyshannon.

The climate is not only colder than the more southern counties, but also more moist, owing to the number and height of the mountains with which the greater part of its surface is overspread. The whole of the northern part of the county is mountainous. Lugnaculeagh, the most elevated of the mountains, rises to the height of 1485 feet; Benbo is 1365 feet high; Lacka, 1315; the Green Mountain, 950 feet. More southerly are Slieve-an-Ierin and Bencroi. Large tracts of ground comparatively level are to be found in the southern part of the county, the greater part of which is well wooded, fertile, and abounding in picturesque scenery. The soil in general is stiff, heavy, cold, and wet. The tops and sides of most of the hills are covered with a thin ferruginous loam, based upon a hard gravel. The valleys, which are in general well watered, are of a quality superior to the hills, deeper in mould, and much more fertile. The more level tracts, already noticed, are a dark rich soil on a limestone bottom.

The county is not more remarkable for its mountains than for its lakes. The principal is Lough Allen, situate in its centre, where narrowest. It is 8 miles long from N.

to S., and 4 where broadest, and may be looked upon as the great reservoir and distributor of all the running water in the county, and the embryo feeder of every canal that may be made to traverse it. Squalls on this lake are violent, and render boating on it hazardous. Lough Allen is not in itself an interesting, or beautiful, or picturesque lake; neither is the scenery on its banks sufficiently bold to make the smallest approach to grandeur; it is merely wild and solitary. It is embosomed in hills of moderate elevation, not picturesque in their outline, nor clothed with wood, and contains a few islets. A few miles to the N. is Lough Clean, or Belhovel Lake, which covers an area of 345 acres, and discharges its waters into Lough Allen by a stream of some magnitude. Several smaller sheets of water are scattered throughout the southern baronies. On the borders are Lough Gill, Lough Melvyn, Lough Cane, and Lough Boffin. The source of the Shannon is a matter of doubt among the local topographers; by some it is placed in the recesses of the Leitrim Hills, where it is said to spring with nearly its full power from a vast gulf, the depth of which has not yet been ascertained; and almost immediately expanding, forms Lough Allen, of which the area is 8900 acres. Issuing from the southern extremity of Lough Allen, this noble river, which is here but 146 feet above the level of the sea, forms the western boundary of the county. The Bonnet rises near Lough Clean, and after a course of about 15 miles through picturesque scenery, falls into Lough Gilly. The small rivers, Bundrows and Brinduff, which separate Leitrim from Donegal and Sligo, contain between their mouths the scanty line of sea-coast belonging to the county. Many other streams, too small to be particularly noticed, and discharging themselves into some of the numerous lakes or larger rivers, afford a copious and perennial supply of water.

The central parts of the county form part of the great Connaught coalfield, which occupies also large portions of the counties of Roscommon, Sligo, and a part of Cavan in Ulster. Before a committee of the House of Commons, Mr Griffith stated that there are three beds of coal in the Lough Allen district, the upper 9 inches, the second 3 feet, and the third also 3 feet. The quality of the coal is not so good as that of either Whitehaven or Newcastle; it is a kind of medium between the open burning, or quick blazing coal of Scotland, and the caking coal of Whitehaven, and is very good for culinary and manufacturing purposes. The principal vein in this county is in Bencroi Mountain, the summit of which is bog. Iron-ore abounds in the Slieve-an-Ierin, or Iron Mountain, so called from the stores of this valuable metal which it contains. On its northern side, where its flanks have been torn by winter torrents, the metal shows itself in considerable quantities, imbedded in strata of limestone. Alternations of shale and sandstone, containing beds of coal, succeed on this and other mountains of sufficient altitude; for it would appear that such a formation had originally extended over the entire district, and that the absence of those members from the lower mountains has been owing to their removal by some abrading and denuding force. At present they remain only on the summits of Slieve-an-Ierin, Lugnaculeagh, Lackagh, and the highest part of the Munterkenny range; and the occurrence of coal in lumps through the sandstone, gravel, and blue clay hills of the south and south-eastern parts of the county, confirms the supposition that a portion of the coal formation has been removed, and points to the N.W. as the direction from which the denuding agent must have proceeded.

The ore in this county is considered as richer than that found in the Arigna valley in Roscommon. It was at one time attempted to be worked, but the failure of timber, and the want of a regular supply of mineral coal, put a stop to the operations. Indications of the same ore are to be found

Leitrim.

Leitrim. in several other parts of the mountainous district, and even in the interior of the plain country, near the Shannon. Lead has been found near Lurganboy. Upon the N. side of Benbo Mountain are pits whence copper has been extracted. Manganese is also found in considerable quantities, as is pipe-clay, yellow ochre, white and brown chalks, clays of various hues, and sand suited for the manufacture of glass. The substratum of the parts of the county N. and S. of the coal and iron district is chiefly limestone, interspersed occasionally with sandstone. Benbo is granitic. The quantity of bog is estimated to occupy 7234 acres. Its general depth is 30 feet, and it rests on a stratum of marl or blue clay. The highest level of any of the bogs above the Shannon at Lough Reagh is 114 feet, that of the lowest 29. All are so far elevated as to admit of drainage. There is a sulphureous spa at Drumsna, formerly in high repute for cutaneous disorders, and considered more effective than that of Swanlinbar. There are also others of the same quality at Annaghduff, Meelock, and Attymanus, and in some other places. Cavan Spa is a chalybeate, issuing from the southern part of a peninsula in the N. of Lough Allen. Oakfield Spa, likewise chalybeate, is near the sea. Both are visited for their supposed sanative qualities.

The population, like that of every other part of Ireland, was progressively on the increase ever since any series of systematic observations have been directed to ascertain it, until the last decennial period. The following are the most authentic statements :—

1760.....	De Burgho	26,142
1792.....	Beaufort.....	50,000
1813.....	Parliamentary census.....	94,095
1821.....	Ditto.....	124,785
1831.....	Ditto.....	141,524
1841.....	Ditto.....	155,297
1851.....	Ditto.....	111,841

It appears, therefore, that between 1841 and 1851 the population of Leitrim decreased 28 per cent., or 8 per cent. more than the decrease which took place in the whole of Ireland.

This population was represented in the Irish House of Commons by six members,—two for the county at large, and two for each of the close boroughs of Carrick-on-Shannon and Jamestown. At the Union the boroughs were disfranchised, and compensation to the amount of L.15,000 awarded to the Earl of Leitrim for Carrick-on-Shannon, or, as it was then called, Carrick-Drumrushe; and for Jamestown, L.7500; to Gilbert King, Esq., and to the Rev. John King, archdeacon of Killala, and the sovereign and burgesses of the burgh of Jamestown, L.7500. Since the Union no change has been made in the number of representatives, and the county now sends but two members to the imperial parliament.

The state of public education, as collected from the parliamentary inquiries in 1821 and 1824–26, may be inferred from the following table :—

Year.	Boys.	Girls.	Sex not ascertained.	Total.
1821.....	3580	1609	...	5,189
1824–6.....	6736	3627	772	11,135

Of the numbers in the latter of these returns, 2147 were of the Established church, 27 were Dissenters, 7757 Roman Catholics, and 1204 whose religious persuasion could not be ascertained. The total number of schools was 242, of which twenty-one, educating 1181 pupils, were maintained by grants of public money; sixty-four, educating 3113, derived their support from private contributions; and the remaining 157 schools, educating 6841 pupils, were supported wholly by the fees of those who received instruction in them.

The number of pupils attending each description of school,

in 1851, was ascertained, by the Census Commissioners, to have been :—

SCHOOLS.	No. of Schools.	Number of Children.		
		Males.	Females.	Total.
National.....	93	2,449	2,024	4,473
Church Education.....	17	295	254	549
Private	52	731	535	1,266
Free	4	41	114	155
Mission	6	41	102	143
Workhouse	4	453	622	1,075
Gaol	1	67	...	67
Total	177	4,077	3,651	7,728

These numbers state the average attendance of pupils during one week; but from the family returns it appears, that the number actually receiving instruction was 12,303; i.e., 6423 males, and 5780 females. The condition of the entire population of the county, above five years of age, as regards rudimentary education, in 1851, was ascertained to be as follows :—

Degrees of Education.	Males.	Females.	Total.
Who could read and write	18,460	8,940	27,400
Who could read only	9,225	11,395	20,620
Who could neither read nor write	22,537	29,558	52,095

The quantity of land under tillage is small, and the plough little used, excepting in the champaign districts. In the other parts the mode of culture is still, to some extent, by the loy, a narrow spade with a long handle. The hills are generally steep, and, though abounding with stones, are tough, and retentive of moisture. The loy penetrates into this species of soil more easily than the common broad spade, and the length of its handle serves as a lever to overcome the resistance of the tenacious soil. Potatoes are planted with a steveen, which is a stake about four feet long and three inches in diameter, tapering to a point at the lower end, near which a cross piece is fixed to rest the foot on whilst pressing the implement into the ground. The seed is dropped into the hole thus made, which is then filled up with mould. Oats are the general crop; barley is but little grown; rye and wheat still less. Flax forms a part of the usual rotation of crops. There are about 14,400 holdings above one acre in extent, and of this number more than 11,500 contain less than 30 acres. There are also about 500 cottiers, or persons holding less than one acre of land.

The extent of land under crops, and the number of acres under each species of crop, in 1854, 1855, and 1856, was as follows :—

CROPS.	1854.	1855.	1856.
Wheat	293	291	396
Oats	26,959	28,780	27,970
Barley, Bere, Rye, Beans, and Pease	323	587	581
Potatoes	23,666	23,537	25,102
Turnips	988	1,075	871
Other green crops	1,626	1,193	1,515
Flax	1,022	718	680
Meadow and clover	27,748	28,598	28,385
Total extent under crops	82,625	84,779	85,500

Tillage farms are small; those for grazing are of considerable size, and are sometimes held by several tenants in common. The grasses are mostly natural, and in general excellent, producing fat and well-flavoured meat, and excellent milk and butter. Dairies of large size are seldom to

Leitrim. be met with, but every small farmer produces butter to dispose of at some of the neighbouring markets. Green food is seldom used. The cattle are housed in some parts from December to May, whilst in others they are left out during the winter.

The quantity of each of the chief descriptions of live stock in the county, in 1854, 1855, and 1856, was:—

Live Stock.	1854.	1855.	1856.
Number of Horses	3,486	3,759	3,838
Cattle	89,102	91,061	89,950
Sheep	19,047	20,578	20,744
Pigs	27,909	20,790	14,704

The usual fence is a drain, backed at one side with a bank of clammy aluminous earth, 3 or 4 feet high. The ditch thus made soon hardens into a consistency nearly equal to brick, and answers every purpose of fencing, except against sheep, in which case it is topped with brushwood. Stone walls are few. Hawthorn hedges are to be met with in some parts. Manures are rich and abundant. Every part has a command of limestone, either solid, or in gravel or marl. The farmers living upon the confined verge of sea-coast within the county industriously take advantage of the sea-weeds, shells, and gravel found there. Much attention is paid to the collection of every kind of manure. The farm-houses are generally long, narrow buildings, of one storey high, with a yard before them, of which the offices form the sides. The repairs are usually made by the landlord, a custom very uncommon in other counties. Leases are generally for three lives, or thirty-one years. Non-alienation clauses are common, and the tenant is sometimes bound down to manure a certain portion of the land.

The manufactures are confined to that of coarse linen, the weaving of which is carried on to some extent. Manufactories of coarse pottery exist about Leitrim and Dromahaire. The only navigable river by which an inland trade can be carried on is the Shannon, the navigation of which, consisting of a series of lakes, short canals, and the magnificent river itself, forms a water communication from Lough Allen to Limerick, and to Dublin by its connection with the Royal Canal at Tarmonbarry. "The proposed most important line of inland navigation which would connect the Ulster Canal and Lough Erne with the Shannon at Leitrim has not been undertaken. The importance of this connection may be estimated by a glance at the map, when it will be seen that the network of inland navigation of the N.E. of Ireland, is separated from the water communications of the S. and centre by the tract which this canal would intersect, and that, consequently, the two systems of traffic, now isolated, would by it be placed in connection. Limerick would thus come into direct communication with Enniskillen and Ballyshannon, on the western, and with Belfast on the eastern coast of Ulster, and a total line of 716 miles of inland navigation be opened out." (*Industrial Resources of Ireland*, by Sir Robert Kane.)

The general food of the peasantry is potatoes and oaten bread, with butter and eggs occasionally, and flesh meat at the great festivals. The clothing is neat, clean, and substantial; the coat usually of native frieze, and the waistcoat and breeches of corduroy. In their general demeanour the peasantry are kind and warm-hearted. They are, like those of most other parts of Ireland, singularly attached to peculiar places of interment. One of the most frequented of these is on a small island near the entrance of the Shannon into Lough Allen, where are the remains of a church. It has been from time immemorial the burying-place for the residents in all the surrounding country; and when access to it is prevented by the stormy state of the lake, the friends of the deceased remain on shore by the putrefying corpse, until the weather become favourable, rather than remove it

for interment elsewhere. The frequent occurrence of fatal accidents in these funeral voyages induced a neighbouring gentleman to have a piece of ground upon the adjoining mainland consecrated as a cemetery, but to no purpose. The survivors preferred awaiting all chances of weather rather than relinquish the idea of depositing the bones of their departed friend with those of his forefathers. The mountainous districts are thickly peopled, but have few resident proprietors. The lowest classes there speak Irish, a language which is understood by about thirteen per cent. of the entire population of the county. The vicinity of the three counties of Leitrim, Cavan, and Sligo to each other formerly gave frequent occasion to party feuds between hostile clans or factions, that seldom terminated without bloodshed, and not unfrequently with loss of life.

There are but few remains of ancient Irish antiquities in this county. The most remarkable are two druidical altars; one very large near Fenagh, the other of smaller dimensions at Letterfyan. They are called by the natives Leaba Dearmud is Graine, or Darby's and Graine's bed. The principal monastic buildings, of which any vestiges can now be traced, are the following:—Creevelea, near the River Bonnet, built by Margaret, widow of O'Rourke, in 1509. The walls, which are nearly entire, have on them some curious figures, and contain several antique monuments. Fionagh, in Fenagh parish, still exhibits a window of fine workmanship; the place was anciently celebrated as a school of divinity, and was resorted to by students from many parts of Europe. A Franciscan friary, at Jamestown, was remarkable, in the eventful period of 1641, as being the place where the Roman Catholic clergy assembled, and nominated commissioners to treat with such foreign powers as were willing to assist them in their struggle against the English government. Clone, near a small river of the same name in Mohill barony, has still some ruins to point out its site. Mohill Abbey, Anaghduff, and Drumleas, have been converted into parish churches. Some others are known only by name. Amongst the military antiquities may be noticed O'Rourke's Hall, at Dromahaire, near the Bonnet, the destruction of which was expedited by using its materials for the construction of the neighbouring castle of Dromahaire, supposed to have been built by Sir William Villiers in the year 1628. Other castles, built by various members of the O'Rourke family, are those of Longfield, Cloncorrick, Castle Cor, and one on the banks of Lough Gill. Woodford House is built on the site of another of the O'Rourks' castles. Manor-Hamilton Castle, built by Sir Frederick Hamilton in 1641, but now in ruins, was by much the largest, best built, and handsomest in the county. Castle John stands on an island in the little lake called Lough Scur. Dunganbuy Castle, near the sea, is of the era of Elizabeth.

The population of Leitrim may be said to be wholly rural: no town in it contains 2000 inhabitants. Carrick-on-Shannon, the county town, where the assizes are held, and all the public business transacted, contains no more than 1366 inhabitants. Though well circumstanced for inland trade, from its situation on a fine navigable river, no advantage is derived from its position. Its only public buildings are a court-house, a jail, a chapel of ease, and a barrack. The mail-coach road to Sligo passes through it. The only other towns whose population exceeds 1000 souls are, Mohill, which contains 1223, and Manor-Hamilton, which has 1227 inhabitants. (H. S.—R.)

LEIXLIP, a post and fair town of Ireland, pleasantly situate on the River Liffey, in the county of Kildare, about ten miles from Dublin. Near it are the ruins of the church and castle of Confy. The castle of Leixlip is beautifully situate on the banks of the Liffey. In the immediate neighbourhood is situate the well-known waterfall, called the *Salmon Leap*, which consists of a succession of rocky ledges, on the Liffey, over which the fish dart at one bound. A

Leland
John
||
Leland,
Thomas.

mile from this is Castletown, the magnificent seat of Mr Conolly.

LELAND, JOHN, a famous English antiquary, was born in London, towards the close of the reign of Henry VII. An orphan at a very early age, he was befriended by a Mr Thomas Myles, who placed him at St Paul's School, under Lily, the famous grammarian. He studied first at Christ's College, Cambridge; and a few years afterwards at All Souls' College, Oxford. After residing for some time in Paris, to increase his acquaintance with Latin and Greek, and to acquire French, Italian, and Spanish, he returned to England, and, entering into holy orders, became chaplain to Henry VIII., who appointed him, in 1530, to the rectory of Popeling, in the marches of Calais, made him his librarian, and in 1533 honoured him with the title of the king's antiquary. By a commission given along with this title, he was empowered to search for all records, manuscripts, and relics of antiquity, in the cathedrals, colleges, abbeys, and priories throughout England. Accordingly, being allowed by a special dispensation to supply his place at Popeling with a curate, he set out on a tour which lasted six years, and afforded him ample and varied materials for study during the remainder of his life. On his return in 1542, he was rewarded by the king with the rectory of Haseley in Oxfordshire; in 1543 he was presented to a canonry in King's College (now Christ's Church), Cambridge, and about the same time to the prebend of East and West Knowle in the Cathedral of Sarum. Leland now withdrew to his house in the parish of St Michael le Querne, London, and devoted himself exclusively to the digesting of his information. Shortly after the death of Henry VIII. in 1547, he fell into a state of insanity, which continued until his death on the 18th April 1552. Some of Leland's papers, after passing through several hands, were deposited by Burton, the historian of Leicestershire, in the Bodleian Library at Oxford in 1632. Others came into the possession of Sir Robert Cotton, and are now, along with the rest of his books, in the British Museum. Leland gained additional fame in his own day as a linguist and a poet. His principal works are,—*A Nueve Yeare's Gift to King Henry VIII. in the 37 yeare of his Raygne*, Lond. 1549; *Commentarii de Scriptoribus Britannicis*, edited by Anthony Hall, Oxon., 1709, 2 vols. 8vo; *The Itinerary*, published by Thomas Hearne, Oxford, 1710-12, 9 vols. 8vo, and reprinted in 1770; and *De Rebus Britannicis Collectanea*, edited by Hearne, Oxon., 1715, 8vo, and reprinted at London in 1770.

LELAND, John, D.D., an eminent Christian apologist, was born at Wigan, Lancashire, in 1691; but soon afterwards removed, along with his family, to Dublin. At an early age, he was appointed minister of a congregation of Presbyterian Dissenters in Dublin. He received the degree of D.D. from the University of Aberdeen. In 1733 he published a pamphlet in reply to Tindal's *Christianity as Old as the Creation*. In 1737 he answered *The Moral Philosopher* of Dr Thomas Morgan; and in 1742 Dodwell's *Christianity not founded upon Argument*. His remarks on Bolingbroke's *Letters on History* appeared in 1753. In the following year, his calm scrutiny of objections, his learning, and solidity of argument, were shown to advantage in his *View of the Principal Deistical Writers that have appeared in England*. Towards the close of his life he wrote an elaborate treatise on *The Advantage and Necessity of the Christian Revelation, shown from the state of Religion in the ancient Heathen World*. Leland died in 1766, leaving behind him a reputation for charity and candour, unembittered by a long life of controversy and dispute.

LELAND, Thomas, the translator of Demosthenes, was born at Dublin in 1722. Entering the university of that city as a pensioner of Trinity College in 1737 he was

elected a scholar in 1741, and a fellow in 1746. In 1763 he was nominated professor of poetry. In 1768 the Lord-Lieutenant appointed him his chaplain, a prebendary of St Patrick's Cathedral, and vicar of Bray. In this new capacity, his energetic and perspicuous eloquence soon rendered him the most admired preacher in Dublin. He died in 1785.

His works are:—*Translation of Demosthenes*, London, 1777; *History of the Life and Reign of Philip of Macedon*, London, 1805; *A Dissertation on the Principles of Human Eloquence*, London, 1764; *Sermons*, 3 vols., Dublin, 1788; and *History of Ireland*, London, 1778.

LELY, SIR PETER, a celebrated painter, was the son of a captain in the garrison of Soest, in Westphalia, and was born in that town in 1617. His father, a native of Holland, was originally called Van der Vaes; but the nick-name of Le Lys or Lely, by which he was generally known, was adopted by his son as a proper surname. After studying for two years under Peter Grebber, an artist of some note at Haarlem, Lely, induced by the patronage of Charles I. for the fine arts, removed to England in 1641. Here he soon became so eminent in his profession as to be employed by Cromwell to paint his portrait. At the Restoration, his genius and gentlemanly manners won the favour of Charles II., who made him his state-painter, and afterwards knighted him. To improve himself by the study of the most excellent specimens of his art, he made his famous collection, the best of his time, containing drawings, prints, and paintings by the best masters. His great example, however, was Vandyck, whom, in some of his most successful pieces, he almost rivals. Lely's paintings are carefully and delicately finished, warm and clear in colouring, and animated in design. The graceful posture of the heads, the delicate rounding of the hands, and the broad folds of the draperies, are admired in many of his portraits. His most famous work is a collection of portraits of the ladies at the court of Charles II., preserved at Hampton Court, and known by the title of the "Windsor Beauties." Of his few historical pictures, the best is "Susannah and the Elders," at Burleigh House. His "Jupiter and Europa," in the Duke of Devonshire's collection, is worthy of note. Lely was nearly as famous for crayon painting. Towards the close of his life, he often retired to an estate which he had bought at Kew, in Surrey. He died of apoplexy at London in 1680, and was buried at Covent Garden church, where a monument was afterwards erected to his memory.

LEMBERG (Pol. *Lwow*, Lat. *Leopolis*), a city of Austrian Poland, capital of the kingdom of Galicia, is situated in a narrow valley on the Peltew, a small tributary of the Bug, 185 miles E.S.E. of Cracow, and 365 E.N.E. of Vienna; N. Lat. 49. 51. 40; E. Long. 24. 2. 45. Lemberg was formerly an important fortress, but its fortifications have been destroyed, and its ramparts planted and laid out in public walks. The town itself is small, but it has four large suburbs, each of which surpasses it in size. Within the town the streets are irregular and narrow, and the houses old; but the suburbs are well laid out, and contain many handsome buildings. The houses are built of freestone, and usually two or three storeys in height. Lemberg is the seat of three archbishops, belonging to the Roman Catholic, the Armenian, and the Greek church; and the number of its ecclesiastical edifices, with their steeples and cupolas, give it, especially when viewed from a distance, an air of grandeur. Besides the 3 cathedrals, it has 13 Roman Catholic churches, 2 synagogues, one of which is the most splendid in the Austrian dominions, a Protestant chapel, and several Roman Catholic and Greek convents. In the Dominican church is a monument, by Thorwaldsen, to the Countess Dunin-Borowska. The University of Lemberg has faculties of theology, law, medicine, and philosophy, and is attended by about 1500 students. The library contains about 50,000 volumes. Among the other educational

Lely
||
Lemberg.

Lemgo
||
Lemon.

institutions are two gymnasia, a Roman Catholic, and a Greek ecclesiastical seminary, a normal school, and a school of arts and sciences. There is a public library of 60,000 volumes, particularly rich in Polish literature. Lemberg is more a commercial than a manufacturing city, though it carries on some manufactures of cotton and woollen stuffs, leather, &c. It is the principal trading town in Galicia, though it is chiefly limited to carrying and commission business, arising from its situation on the high road from Odessa to Silesia and Warsaw. Several important fairs are held here, the most important of which is that called *Drei Königs Messe*, which lasts for six weeks from the 14th of January. A great trade in corn and cattle is also carried on. Pop. (1849) 75,000, of whom about 20,000 were Jews.

LEMGO, a town of Germany, principality of Lippe-Detmold, on the Bega, 6 miles N. of Detmold. It has an antique appearance, and is surrounded by an old wall with seven gates. The Rathhaus and the church of St Nicholas are admirable specimens of Gothic architecture. It carries on a trade in wool, linen, leather, and meerscham-pipes, especially the last. Pop. 4200.

LEMNOS, or STALIMENE, an island in the Ægean Sea, belonging to Turkey, and situate in N. Lat. 40., E. Long. 25. Its surface is very rocky, and displays distinct traces of volcanic action. Area about 150 square miles. Its general form is that of an irregular quadrangle, but it presents the outline of two peninsulas connected by a narrow isthmus. The two indentations at the point of junction are the principal harbours, that on the N., St Antonio, affording safe mooring for large ships. A third indentation, the Bay of Kudia, on the S. side of the western peninsula, is also of some importance. The interior of the island is exceedingly barren, with the exception of some small narrow valleys in the S. and W. Where productive, it yields corn, wine, oil, and some fruit.

Lemnos is supposed to have been first peopled by Thracians; and it is recorded that it was subjugated by Miltiades, after he had taken the Chersonesus. It is fabled as the spot on which Vulcan fell when Jupiter cast him from Olympus; and its volcanic appearances have given rise to the fiction that there the ejected god established his workshop. An argillo-silicious earth, called *Terra lemnia*, mentioned by Galen, has attained great celebrity as a medicine, and is still much esteemed by Turks and Greeks. Pliny mentions a labyrinth with 150 columns, the remains of which existed in his day.

The Greek Church is the church of the people, a bishop of which resides at Lemnos, the capital (the ancient *Myrina*). This town stands on the W. coast, and has three Greek churches, a harbour, and a building-dock. It is protected by a citadel. Pop. of the island from 10,000 to 12,000.

LEMON, the fruit of *Citrus Limonum* (see BOTANY, Index), is a native of Asia, and was brought to Europe by the Crusaders. Like most of its tribe, the lemon produces under cultivation a great number of varieties. Several are known in commerce. The principal are,—the Wax Lemon (*Citrus Limonum ceriescum* of Risso): this is the *smooth-peeled one*, most generally found in the markets; its rind is thick. The Bignette Lemon (*Citrus Limonum Bignetta* of Risso) is a thinner-peeled fruit than the wax lemon, less oval in shape, and more blunt at the point; the colour of the rind is less clear, and is usually tinged with green. It is cultivated more largely than any other variety, as it yields a larger quantity of juice, and is a most abundant bearer. The Clustered Lemon (*Citrus Limonum racemosum* of Risso) is the least oval of the imported lemons, but the nipple-like point is fully developed. The rind is thick, and has a bright yellow colour. The pulp is less agreeable than the varieties previously mentioned. One

or two other varieties, as the Imperial and Gaeta lemons, are occasionally brought to this country, but not in any considerable quantities.

The lemon is extensively cultivated in Sicily, Italy, Spain, Portugal, and the S. of France. By far the greater number imported come from Messina and Palermo. The average imports into Great Britain are about 4000 boxes, or 5000 bushels.

Besides the fruit, the rind of the fruit comes either pickled in salt or already candied. From Sicily, Naples, and Lisbon we receive nearly 70,000 lb. of the essential oil of lemon, yielded so abundantly by the flavedo of the peel. In order to obtain it, the flavedo is grated off, and being put into a horse-hair bag, a yellow turbid oil is forced out by pressure; this, after standing some time, deposits a thick sediment, and is then decanted and afterwards filtered.

Lime juice is another of the products of the lemon, and is of great value as a preventive and cure for scurvy. It is received either fresh, as expressed from the fruit, in which state it is a turbid light yellow coloured liquid; or in a state of concentration from boiling. This concentrated lime juice is a thick coffee-brown coloured liquid, and is chiefly consumed in the manufacture of the crystallized citric acid, which exists in greater abundance in the lemon than in any other fruit.

Citric acid is separated from the juice with great ease, owing to the readiness with which it enters into combination with chalk, forming citrate of lime. To this sulphuric acid is added, and forms the insoluble sulphate of lime, from which the citric acid is easily obtained by washing, and subsequent crystallization. Citric acid used in the manufacture of various pharmaceutical preparations, in combination with iron, quinine, potash, &c. (T. C. A.)

LEMON, *Salt of*, a term improperly applied to bin-oxalate of potass, or salt of sorrel. It is prepared, in Switzerland and the neighbouring countries, from wood-sorrel; about 60 or 70 lb. of the mature plant yielding about 5 oz. of the crystallized salt. Some persons, deceived by the vulgar name, have used this substance to acidulate punch; but it is a dangerous practice, for the binoxalate of potass is an active poison. It is best known in this country as a means of removing ink-spots from linen. When an ink-spot is washed with an alkaline soap, it forms a yellow *iron-mould*, as it is called, in consequence of the oxide of iron, which is the basis of the ink, attaching itself to the cloth, while the tannic acid of the ink is removed by the alkali of the soap. The oxalic acid of the binoxalate of potash unites readily with most of the metallic oxides; and in the case of an iron mould, forms a colourless oxalate of iron, which being soluble, is readily removed from the linen. (C. T.)

LEMONNIER, PIERRE (CLAUDE) CHARLES, a diligent and accurate astronomer, born at Paris, on the 23d of November 1715, was the son of Peter Lemonnier, of St Sever, in the province of Normandy.

His father was a professor of philosophy in the College d'Harcourt, and member of the Academy of Sciences. He distinguished himself, as a teacher, by his activity in promoting the introduction of mathematical reasoning into the Cartesian philosophy. Under such auspices, the son might have enjoyed facilities for the cultivation of any of the sciences; but he soon showed a decided preference for astronomy, and began to be a practical observer before he was sixteen. In the month of November 1732, Mr Fouchy procured him the use of a mural quadrant of 3 feet radius, and he soon applied himself with diligence to the determination of the sun's greatest equation, an investigation which he continued for many years; and in 1741 he found the equation to amount to $1^{\circ} 55' 31''$; a quantity differing only by 7" from Delambre's latest determination.

He presented to the Academy of Sciences, in 1735, an elaborate map of the moon, accompanied by some remarks;

Lemonnier.

and, in the month of April of the following year, before he was twenty-one years old, he was made a member of the Academy, in the character of adjunct geometrician. He continued to be a constant contributor to its *Memoirs* for more than fifty years. The winter of 1736 and 1737 he passed at Torneo, with Clairaut and Maupertuis, as a member of a committee appointed by the Academy for measuring a degree in Lapland; and he was not less zealous than any of his colleagues in the execution of that arduous undertaking.

He is considered as having effected, in conjunction with Lacaille, a complete reformation in the practical astronomy of France. He entered very early into correspondence with the English astronomers of the day; they had carried their instruments and modes of observation to a higher degree of perfection than their neighbours; and Lemonnier was of great use to the science in making known to his countrymen the practical methods of Flamsteed, and in introducing the instruments of Graham and Bird. In April 1739 he was made a foreign member of the Royal Society of London, and for the last twelve or fourteen years of his life he is said to have been the senior member of the society. He was the first that introduced the effects of nutation, then lately discovered by Bradley, into the solar tables; and he complained bitterly of Lacaille's injustice in not giving him due credit for the improvement.

The Duc de Noailles made him known to the King of France, who was fond of his company, and showed him many kindnesses. In 1742, he gave him apartments at the Capucins in the Rue St Honoré, where he continued to live till the Revolution. On another occasion, when he had taken great pains to fix an accurate meridian at St Sulpice, the king made him a present of 15,000 livres, which he expended in the purchase of instruments, as the greatest luxury that he was capable of enjoying.

The places of the stars, which he determined in 1740, served Lalande for the purpose of computing their proper motions, though they differed a little from the results of Bradley's observations. About 1746 he was much engaged in examining the inequalities of Saturn, produced by the attraction of Jupiter; and Euler employed his computations in the theory which obtained a prize in 1748; each confirming the accuracy of the other. He continued to observe the moon, without intermission, for fifty years, though a small part only of his observations was published.

In the year 1748 he went to England, partly for the purpose of obtaining further information from a personal acquaintance with the astronomers and opticians resident in London, and partly in order to observe the solar eclipse of that year, in a situation where it would be very nearly annular. He proceeded, accordingly, to Scotland with the Earl of Morton, accompanied by Short the optician, and they observed the eclipse together at Aberdour, an ancient residence of Lord Morton's, in Fifeshire. They obtained their time from the College at Edinburgh, where there was a transit instrument, by means of the flash of a cannon fired from the castle at twelve, and another five minutes after. Lemonnier was particularly anxious to measure the moon's diameter, which "he found $29' 47\frac{1}{2}''$," agreeing precisely with the computed diameter, and not requiring any correction for the supposed effects of irradiation. A similar remark was made by a very accurate practical astronomer in the eclipse of 1836.

In order to verify the position of his mural quadrant, which was of eight feet radius, and made by Bird, Lemonnier felt the advantage of having a moveable one to compare with it, and he procured a block of marble 8 feet by 6, and 15 inches thick, turning on an axis, to which he fixed his smaller instrument of 5 feet radius, in order to be able to reverse its position. He devoted a considerable portion of his time to the investigation of the laws of mag-

netism, and especially to the variation of the compass; and he endeavoured to ascertain the effect of the moon's influence on the winds, and on the atmosphere in general.

Lemonnier had long disputed the accuracy of the Parisian base, measured by Cassini and Maraldi, but he was at last convinced that his objections were groundless. He was originally a most zealous friend and patron of Lalande; but afterwards, having taken offence at some slight cause, he refused to see him for many years. In fact, he appears to have been somewhat obstinate and irritable; but he is said to have had genius, zeal, activity, and intelligence, as well as credit in the world, and reputation among men of science. He was a voluminous writer; he had much learning and sagacity, but he often wanted precision in his language and his reasoning. In November 1791 he had a paralytic attack, which terminated his scientific career, though he survived it till the 2d of April 1799, when a second stroke carried him off, at Héril, near Baieux. He was made, in the meantime, one of the 144 original members of the National Institute, as a testimony to the merit of his past labours.

He had married, in 1763, Mlle. de Cussy, a lady of very respectable family in Normandy. He had three daughters; the first married M. de Parfouru, who was an early victim of the Revolution; the second the celebrated Lagrange; and the third her uncle, Lemonnier the physician, who was also a man of considerable science, and a member of the Royal Society of London.

From 1735 to 1790 there were very few volumes of the *Memoirs* of the Academy without one or more of Lemonnier's papers; but though not unimportant in the aggregate, they are somewhat uninteresting in the detail. They relate almost exclusively to astronomical observations; eclipses, occultations, appulses, oppositions, and conjunctions; solstices, longitudes and latitudes, with some accounts of astronomical instruments and apparatus. There are also some memoirs relating to the sun's equation and diameter, and on his place, as compared with Arcturus: on the motion of Saturn, and on his fifth satellite; on the expansion of wooden measures; on the transit of Venus, and on the diameter and the tables of that planet; on Euler's formula for parallax; on the variation of the needle; on lunar altitudes; on the tides; on horizontal refraction; on Saturn's ring; and on some currents of wind. He also published separately some extensive works, which acquired considerable celebrity.

1. The first was his *Histoire Céleste*, 4to, 1741, comprehending the interval from 1666 to 1685, and containing an account of a transit instrument of Graham's construction.

2. *Théorie des Comètes*, 1743, in 8vo, including a translation of Halley's work on comets, together with a method of computing the orbit from three observations.

3. *Institutions Astronomiques*, 4to, 1746; an improved translation of Keill's *Astronomy*, which long continued to be the best elementary treatise in the French language. It contains also solar tables, and a variety of other additions derived from observation.

4. *Observations Astronomiques*, part i., 1751; ii., 1754; iii., 1759; iv., 1775.

5. A Letter on the Theory of the Winds, in Halley's *Tables*, published by Chappe.

6. *Nouveau Zodiaque, réduit à 1755*, Paris, 1755, in 8vo, containing 31 pages of charts, much more complete than those of Senex, and superseded by some very late publications only.

7. A History of Astronomy in the *Traité d'Aberration de Fontaines des Crutes*.

8. *Observations pour la Mésure du degré entre Paris et Amiens* 8vo, 1757.

9. *Abrégé du Pilotage*, par Goubert, 1766, in 4to, with additions.

10. *Astronomie Nautique Lunaire*, 8vo, 1771.

11. *Exposition des Moyens les plus faciles de résoudre plusieurs questions dans l'Art de la Navigation*, 1772, in 8vo, employing very generally a table of verse sines, and greatly recommending the use of Gunter's scale for nautical computations.

12. *Essai sur les Marées*, 1774, in 8vo, particularly describing the effects of the tides at Mont St Michel, and on the neighbouring flat

Lemonnier.

Lena sands, and including also some considerations on refraction and on magnetism.

13. *Description et Usage des principaux Instrumens d'Astronomie*, 1774, folio, forming part of the collection of *Arts et Métiers*.

14. *Atlas cœleste de Flamsteed*, 1776, in 4to, revised.

15. *Lois du Magnétisme*, 2 parts, 8vo, 1776-8, with an elaborate chart.

16. *Traité de la Construction de Vaisseaux*, par Chapman, 1779, folio, from the Swedish, and said to be less perfect than the translation of Vial du Clairbois.

17. *Mémoires concernant diverses questions d'Astronomie et de Physique*, 4 parts, 1781-84-86-88, in 4to.

18. *De la Correction introduite pour accourcir la Ligne sèche du Lock de dix-huit pieds*, 8vo, 1790.

19. *Lettre au sujet d'une Eclipsé*, Paris, 1791; together with some remarks on navigation, and on the currents of the South Seas, all apparently from the Memoirs of the Academy. The eclipse, which was observed as annular in China, should have been total, according to the computed distance of the luminaries concerned. (T. Y.)

LENA, a large river of Eastern Siberia, rises from a small lake among the Baikal Hills, about 50 miles N.E. of Irkutsk, and falls into the Arctic Ocean by several mouths between N. Lat. 72. and 73., and E. Long. 125. and 130. Its source is more than 2000 feet above sea-level, and its length is estimated at about 2400 miles. For the first 1000 miles to Yakutsk it flows from S.W. to N.E., and receives as tributaries on the right the Vitim and Olekma. It then turns round to the N.W., receives the Aldan on the right, and the Vilhoui on the left, and afterwards takes a northern but winding course to its entrance into the sea. The Lena, as its name signifies, is a "sluggish" river, with steep banks and great depth. It is said to be navigable at Kachuga, only 50 miles from its source. It is frozen over for nine months in the year, when sledges are employed as excellent substitutes for boats. Islands are very numerous in its course, as well as at its embouchure, and obstruct the navigation exceedingly. The upper valley of the Lena is covered with pine forests, affording excellent timber for boat-building; but as the river approaches the sea its shores become sterile, flat, and dreary, and thinly peopled. Near its mouth the river is from 3 to 4 miles in width, and, according to Ritter, its entire basin covers an area of about 800,000 square miles.

L'ENFANT, JACQUES, a French Protestant divine, the son of the Protestant pastor of Chatillon-sur-Seine, was born at Bazoches in Beause, a district of the ancient province of Orleannois, on the 13th April 1661. After studying at Saumur and Geneva, he completed his theological course at Heidelberg, and, receiving ordination in 1684, was appointed pastor of the French Protestant church in that city, and chaplain to the Dowager Electress Palatine. In 1688, on the descent of the French under Turenne into the palatinate, L'Enfant, who had incurred the dislike of many of his countrymen by two letters which he had written against the Jesuits, retired to Berlin. Here Frederic, the Elector of Brandenburg, afterwards King of Prussia, appointed him one of the ministers of the French Protestant church, an office which he held till his death. Visiting England in 1707, it is said that he had the honour of preaching before Queen Anne, and of being requested by her to enter the Church of England, and become her chaplain. Declining this offer, he returned to Berlin, and in 1710 became chaplain to the King of Prussia, and councillor of the high consistory. In search of materials for his historical works, he visited Helmstadt in 1712, Leipsic in 1715, and Breslau in 1725. Through the influence of the King of Prussia he had also access to the archives of the corporation of Basel. He was one of the chief supporters of the *Bibliothèque Germanique*, which was begun in 1720, and wrote the preface. On the 29th of July, 1728, he was suddenly attacked with paralysis, which caused his death on the 7th August following.

LENNEP, a manufacturing town of the Prussian province Düsseldorf, capital of a cognominal circle, on the

Lennepe, a tributary of the Wipper, 21 miles E. by S. of Düsseldorf. Woollen and cotton stuffs are manufactured in considerable quantities, and a trade in wool, iron, and wine is carried on to some extent. Pop. 7064.

LENNOX, or DUMBARTONSHIRE, a county of Scotland. See DUMBARTONSHIRE.

LENNOXTOWN, a town of Scotland, Stirlingshire, at the foot of the Campsie Hills, 12 miles N. of Glasgow by railway. It has several calico-print and alum works, besides bleachfields, collieries, and lime quarries in the neighbourhood. Pop. (1851) 3108.

LENT, the name of one of the festivals celebrated in the Roman Catholic, and many of the Protestant churches. It derives its name from an Anglo-Saxon word, signifying spring. As a religious festival, it is intended to commemorate the fasting of our Saviour forty days in the wilderness. It lasts for forty days before Easter, and is therefore moveable with that term. See EASTER, CALENDAR, &c., &c.

LENTIL, the seeds of *Errum lens* (natural order *Leguminosæ*). The lentil is closely allied to the tare, and is probably the most ancient of all the food products which man derives from the pea-tribe. The *red pottage* in Gen. xxv. 34, is the small lentil decorticated, as it is sold at the present day in the bazaars of India.

Pliny mentions two kinds of lentils grown in Egypt, one rounder and blacker than the other. These were, probably, only varieties resulting from cultivation. Three such are cultivated in France, where, as in most Roman Catholic countries, this kind of pulse is extensively used during Lent; to which season, as some suppose, it gives its name.

The lentil is a native of Europe, Asia, and Northern Africa; or, at all events, it is naturalized in those parts of the world. It is cultivated occasionally in some parts of England, but chiefly as a fodder plant. The ripe seeds are very nutritious, and contain a large proportion of gluten. They are frequently imported from Alexandria for cattle-feeding; whilst, for culinary purposes, the larger and lighter-coloured varieties are imported from France and Germany, where considerable attention is paid to their cultivation and harvesting. In Egypt the lentil forms a large proportion of the general food of the inhabitants, and the haulm is used for packing purposes.

The empirical preparation called *Revalenta Arabica*, has been proved to be nothing but the meal of decorticated lentils; a food by no means well adapted to all constitutions, especially those of infants.

The quantity of starch in the lentil is very considerable; and, in addition to the gluten, renders this pulse one of the most nutritive of vegetable food products. Lentils are, however, heating if used much. The starch, according to Einhoff, is nearly one-third its weight.

The importation of lentils is very irregular; but 2000 qrs. is the largest quantity imported in one year. (T. C. A.)

LENTINI (the ancient *Leontini*), a town of Sicily, intendency of Syracuse, on the River Porcari, 20 miles N.W. of Syracuse. It was founded in the first year of the thirteenth Olympiad, by a colony of Chalcidians, and, when taken by Marcellus, was one of the chief places in Sicily. It retained its importance till the earthquake of 1693, by which it was completely ruined. The neighbourhood is productive, but unhealthy. The inhabitants are chiefly engaged in fishing on the neighbouring lake of the same name. Pop. about 5000.

LEO I., FLAVIUS, surnamed the *Great*, and the *Thracian*, was born about A.D. 400, in the country of the Bessi, in Thrace. On the death of the Emperor Marcianus, in 457, being then only a military tribune, he was recommended by the patrician Aspar to the soldiers, who proclaimed him emperor. His election was ratified by the senate, and he was crowned by Anatolius, Patriarch of Constantinople, thus introducing the custom, which afterwards became so prevalent, of Christian princes receiving their crowns from the

Lennox
||
Leo I.

Leo III. hands of bishops. No sooner had Leo ascended the throne, than he resisted the influence which Aspar sought to exercise over him, by telling him that "it was unbecoming for a prince to resign his own judgment and the public interest to the will of a subject." In 466 the Huns, invading Dacia, were defeated by his generals, Anthemius and Anagastus, with the loss of their chief, Dengizec, son of Attila. In 468 Leo, in concert with Anthemius, now Emperor of the West, equipped a large naval armament against the Vandals of Africa, who, under their king, Genseric, had long been the scourge of Italy and the Mediterranean. His fleet, consisting of 1113 ships, having each 100 men on board, was intrusted to the command of his brother-in-law, Basiliscus, who, after a prosperous passage, disembarked his troops safely at Cape Bona, about 40 miles from Carthage, the capital of the enemy. Genseric, feigning a desire to submit, requested and obtained from Basiliscus, a truce of five days. During that interval, favoured by the wind and the darkness of night, the fleet of Genseric, with several fire-ships in tow, attacked the Roman vessels, burnt and sunk one-half of them, and thus caused the entire failure of the expedition. A public opinion that Aspar had in some way effected this disastrous defeat, afforded Leo a pretext of getting rid of this dangerous king-maker. Taking advantage of a burst of public odium against Aspar, he ordered him, and one of his sons, to be put to death, and thus left a foul stain upon his own memory. Under pretext of revenging this murder, the Goths invaded Thrace, and, though overpowered after two years, disturbed the last days of Leo. He died in 474, leaving the crown to Leo, the infant son of his daughter, Ariadne. Though scarcely deserving of his surname, the *Great*, Leo was active, enlightened, and prudent; and though illiterate himself, was a liberal patron of learned men.

LEO III., *Flavius*, surnamed the *Isaurian*, Emperor of Constantinople, was born in Isauria, and was originally called Conon. His father, a wealthy grazier, emigrated from Asia Minor to Thrace, and obtained for his son the rank of a spatharius in the army of Justinian II., where his eminent abilities soon excited the jealousy of the emperor. From Anastasius II. he received the command of the troops in Asia; and when that emperor was deposed in 716 by Theodosius III., Leo, marching to Constantinople, compelled the usurper to resign, and the vacant crown was conferred upon himself, by the suffrages of the soldiers, in March 718. Soon after his accession, the Arabs, in large hordes, invested Constantinople so closely by land and sea, that the final capture of the city was considered certain. The Emperor, however, sailing out of the Golden Horn with his galleys, burnt some of the hostile vessels by means of his fire-ships, and threw the rest into confusion. After sustaining severe losses, in two other naval engagements and in one land battle, the Arabs in 720 were obliged to raise a siege which had lasted two years. Meanwhile, the deposed Emperor Anastasius II., expecting the downfall of Leo, had formed a treasonable conspiracy which was discovered in 721, and punished capitally. Shortly before this period the dislike entertained by the Mohammedans and Jews against image-worship had gradually spread among the Eastern Christians, and had originated the sect of the Iconoclasts, or image-breakers. Adopting the views of this sect, Leo issued a general edict commanding the removal of images from all the churches of the empire. His chief object was to reform the church; but he also undoubtedly aimed at drawing the Jews and Mohammedans within the pale of Christianity, and thus increasing the strength and splendour of the empire of the East. This edict met with general opposition. Instigated by Pope Gregory II., the Italians refused to obey, and when Paulus, exarch of Ravenna, was ordered to employ force, resisted, and repulsed him. Peloponnesus and the Cyclades rebelling, sent a fleet to invest Constantinople, but were

worsted in a sea engagement, and compelled to submit. In Constantinople, also, an insurrection arose, which, after causing much bloodshed, was quelled by the capital punishment of the ringleaders, and the deposition of the Patriarch Germanus. In 731 a council held at Rome by Gregory III. condemned the Iconoclasts; and incited in Italy so much opposition to Leo, that he sent a powerful armament against that country. The armament failed, and Ravenna and the exarchate were seized by the Lombards. Leo in revenge transferred, in 734, Greece, Macedonia, and Illyria from the patriarchate of Rome to that of Constantinople, an act which eventually caused the schism between the Greek and Roman churches. The remainder of his life was disquieted by a protracted war with the Arabs. He died of dropsy in 741.

Leo's character, much depreciated by the advocates of image-worship, is best elucidated by the facts of his life. His rapid rise from obscurity to the pinnacle of power, his firm and successful administration, amid foreign assaults and domestic plots, and his resolute prosecution of the reformation of the church, all indicate a wise and provident policy, great vigour, and decision of will. His early military life, although it rendered him cruel and obstinate, did not taint the purity of his manners.

LEO V., *Flavius*, surnamed the *Armenian*, was of Armenian descent, and son of Bardas Patricius. Serving as a general under Nicephorus I., he was banished for treachery, but in 811 was recalled, and appointed *dux Orientis* by the succeeding emperor, Michael I. This favour was repaid with ingratitude; for Leo, after gaining some reputation in his wars with the Arabs, accompanied his sovereign, in 813, on an expedition against Crum, King of the Bulgarians, and taking advantage of the disaffection of the army during a battle with the enemy near Adrianople, withdrew with the forces under his command, and left Michael to total defeat. Having thus stripped the emperor both of power and reputation, Leo was called upon by his army to mount the throne; and when he pretended to hesitate, his friend, Michael the Stammerer, confronted him with his naked sword, exclaiming, "With this sword will I open the gates of Constantinople, or plunge it into thy heart, if thou refusest any longer to comply with the just wishes of thy comrades." Leo marched into Constantinople, and was crowned in 813, without any opposition. In 814 the Bulgarians threatening the capital, were defeated at Mesembria; and, in the following year, Leo again repulsing them, invaded their territory, and effectually subdued them. In the peace that ensued, all his efforts were exerted to effect the equal administration of justice, and the suppression of image-worship; but his punishment of the latter offence was so severe and unrelenting, that even his best friend, Michael the Stammerer, became his enemy. Having organized a conspiracy, Michael was betrayed, tried, and condemned to be burnt. On Christmas Eve he was dragged to the place of execution; but when about to meet his fate, was remanded to prison at the entreaty of the empress, who was unwilling that the sacred season should be profaned by such a horrible death. During the night, his friends having formed a plot, appeared at the palace chapel on the ensuing morning, in the garb of priests, and while the emperor, as was his custom, began the chant, they fell upon him, and in spite of his desperate defence with the large cross, murdered him, A.D. 820. He was succeeded by Michael the Stammerer. Unlettered, and ignorant of the laws of government, Leo erred in introducing into his civil administration the severe and condign punishment of military discipline.

LEO of *Byzantium*, an historian of the time of Philip, and probably of Alexander, occupied an important office in the Byzantine commonwealth, during its invasion by Philip. According to Hesychius of Miletus, he was general of the forces. During the siege of his native city, or shortly after

Leo, V.
||
Leo of Byzantium.

Leo Dia-
conus
||
Leo of
Thessalo-
nica.

it, he was sent on an embassy to Athens. Byzantium, when on the eve of being captured, was succoured by the Athenian auxiliaries under Chares, B.C. 340, and afterwards under Phocion, and Philip was compelled to withdraw. After this repulse, the king, according to Suidas, accused Leo to his fellow-countrymen of having designed to betray the city for money; and Leo, afraid of falling a victim to popular fury, hanged himself. Hesychius of Miletus, however, states that he died during the siege, before the arrival of the Athenians under Chares. On both of these statements considerable doubt is thrown by Suidas and Eudocia representing Leo as the author of two works,—*Tὰ κατὰ Φίλιππον καὶ τὸ Βυζάντιον* (*The affairs of Philip and the Byzantines*); and *Tὰ κατ' Ἀλέξανδρον* (*The Exploits of Alexander*). The other works commonly attributed to him are,—*Τευθρανικόν* (*Teuthranicum*); *Περὶ Βησάλου* or *Βησαλῶν* (*De Besalo* or *Besæo*); *Ὁ ἱερὸς πόλεμος* (*The Sacred War*); and *Περὶ στάσεων* (*De Seditionibus*, or *De Statibus*). None of his works are extant.

LEO *Diaconus*, or the *Deacon*, an historian of the tenth century, was born at Caloë, a town of Asia Minor, probably about A.D. 950. From his history we learn that he was studying at Constantinople in 966; that he was in Asia in 973 or 974, when Basilus I., Patriarch of Constantinople was deposed, and that in 981 he accompanied the Emperor Basilus II. on his expedition against the Bulgarians. We infer also, from some of the events he mentions, that he must have lived at least till 993. His works are,—*Ἱστορία*, *Oratio ad Basilium Imperatorem*, and *Homilia in Michaelæm Archangelum*.

Of these, the two last exist only in manuscript. His *History* was first published at the expense of Count Nicolas Romanzof, Chancellor of Russia, accompanied with a preface, a Latin version, notes, and engravings from ancient gems, by C. B. Hase, Paris, 1818. This edition, without the engravings, was reprinted in the Bonn edition of the *Corpus Historiæ Byzantinæ*, 1828.

LEO *Grammaticus*, a Byzantine historian of the tenth century, is said to have been governor of Cibra under Constantine VII. His work, entitled *Χρονογραφία τὰ τῶν νέων βασιλέων περιέχουσα* (*A Chronography, comprising the Acts of the more recent Emperors*), is a continuation of Byzantine history from the accession of Leo V., the Armenian, A.D. 813, to the death of Romanus I. in 948. Published along with Theophanes, under the superintendence of Combéfis, Paris, 1655, in the Parisian edition of the *Corpus Historiæ Byzantinæ*, it was reprinted at Venice, 1729. Leo probably wrote his History in the time of Romanus II.

LEO of *Thessalonica*, surnamed the *Philosopher*, a learned ecclesiastic of the ninth century. The date and place of his birth are unknown. He studied grammar and poetry at Constantinople, and arithmetic, rhetoric, and philosophy in the island of Andros, under Michael Psellus. By exploring all the monastic libraries in continental Greece, and perusing their valuable contents, he amassed a large stock of general information, and, returning to Constantinople, became a teacher. One of his pupils having been captured in war by the Moslems, and becoming known through his geometrical acquirements to the caliph, who was a patron of learning, extolled the attainments of his master Leo so highly that he was despatched with a letter to the Philosopher inviting him to Baghdad. Afraid to correspond with an enemy, Leo contrived that the letter should be laid before the Emperor Theophilus, and was thus recommended to royal patronage. The emperor appointed him public teacher or professor, and afterwards ordered the Patriarch Joannes, the celebrated Iconoclast, and a kinsman of Leo's, to consecrate him Bishop of Thessalonica. On the death of the emperor, and the instalment of his widow Theodora in the regency, he was deposed from his see for his icono-

clastic opinions, but was afterwards appointed to the management of a mathematical school, established in Constantinople by the Cæsar Bardas. The latest period of Leo's life of which we have any notice is 869. The date of his death is unknown.

The only extant works that can with any probability be ascribed to Leo the Philosopher are several astrological MSS. existing in various European libraries.

LEO X., *Pope*, the second son of Lorenzo de Medici, was born at Florence in December 1475. His original name was Giovanni or John. Having taken the tonsure at the early age of seven, he was presented with two rich abbey, through the influence of his father with Louis XI. of France, and Pope Sixtus IV. Many other benefices followed; and, in 1488, when only thirteen, he was raised to the rank of cardinal by Innocent VIII. Hitherto he had been under the tuition of Chalcondylas, the famous Greek historian, and Angelo Poliziano; and, being naturally sedate even in his youth, he had evinced that love of classical learning for which he was afterwards so noted. He was now sent to Pisa to study theology, and, on his return in 1492, was invested with the purple, and soon afterwards went to reside in Rome as a member of the sacred college. On the accession of Pope Alexander VI., whose election he had opposed, he returned to Florence, and remained there until the invasion of Italy by Charles VIII. of France obliged his family to flee in 1494. Repairing to Bologna, he afterwards, in 1499, travelled through France and Germany, enjoying the society of learned men, and indulging his love of literature and the liberal arts. Returning to Rome, he lived in strict seclusion until the accession of Julius II. in 1503. Having recommended himself to the pope by his activity in public affairs, he was appointed governor of Perugia; and, in 1511, for his fidelity in this administration, he was rewarded with the high office of commander of the papal forces in the holy league against France. At the battle of Ravenna, in 1512, he was taken prisoner and conveyed to Milan, but, recovering his liberty soon afterwards, he returned to Bologna, where he governed the district as papal legate.

The death of Julius II., in 1513, recalled him to Rome, and in March of the same year he was elected his successor in the pontificate, and assumed the title of Leo X. No sooner was he seated in the papal chair, than the invasion of the north of Italy, by the French troops of Louis XII., summoned him to exercise his talent in the field. Mainly by means of Swiss auxiliaries the French were defeated at Novara, and Louis XII. was forced to seek absolution from the papal power. The peace that followed was spent by Leo in patronizing learning and the fine arts. Not long after his accession he had appointed Bembo and Sadoleti papal secretaries. He revived the Roman University by means of rich presents and valuable endowments, and by attracting to it eminent professors from different lands. A Greek press was also established; and by offering large rewards, he incited a search for ancient manuscripts in all the libraries and cloisters of Europe. In 1515, however, Leo's attention was diverted to the French, who, under the command of their young monarch, Francis I., had invaded Italy with the intent of retaking Milan. The Swiss auxiliaries of the pope were defeated at Marignano, 14th September 1515, and the French entered Milan, and seized the duchy. Seeing his own power in jeopardy, Leo, with characteristic prudence, and despite the advice of his cardinals, hastened to the king at Bologna; and there was concluded the concordat in which the pope, in return for the ceding of Parma and Piacenza to the French, shared with the king the rights of the Gallican church. During this crisis the Duke of Urbino, who was receiving the pope's pay, had proved treacherous; and in 1516 Leo, after a hard struggle, stripped him of his duchy, and, by conferring it upon his

Leo X.

Leo,
Leonardo
||
Leoben.

own nephew, increased the influence of his family. In 1517, alarmed at a conspiracy that had been formed to poison him, he created thirty-one cardinals in the same day, chiefly from among his own relations. To furnish money for his extravagant pleasures, in the same year he authorized the sale of indulgences, a practice that first roused the opposition of Luther. Desirous of recovering Parma and Piacenza, which he had ceded to Francis I., he formed, in 1521, a league with Charles V., stipulating, as one of the conditions, that Luther should be deprived of the emperor's protection. The allied armies were successful; the French were driven out of Milan, and Parma and Piacenza retaken. Leo, soon after receiving the welcome tidings at his favourite villa Malliana, returned to Rome, and there, amid the festivities and rejoicings on account of the success, was attacked by a sudden malady, which, after eight days, closed his career on the 1st December 1521.

Leo X. has been happily named by Ranke a child of fortune. After his auspicious birth and influential patrons had started him on the highway to preferment, a fair amount of prudence and conduct easily led him to his exalted position; and common policy, with little effort, enabled him to hold his seat. His greatest weakness was his excessive devotion to pleasure; and this being chiefly intellectual and æsthetical, was the cause, perhaps, of his greatest virtue—his liberal patronage to men of genius. During his autumnal residence in the country, the intervals between hawking, hunting, and fishing, were pleasantly squandered in listening to musicians, and improvisatori. When theatres and festivals failed to please in winter, the writings of Machiavel, the poems of Ariosto, and the paintings of Raphael, were sources of new and equally eager pleasure. Even his political activity, never following matters into details, and exercising only the nobler mental faculties, gratified his ruling passion. His heavy debts rendered him unpopular; while his neglect of religious duties, and his refusal of the sacraments on his death-bed, gave, perhaps, sufficient reason for the current belief that he was a sceptic. His chief claim to remembrance is founded on the striking events of the age in which he lived. (Roscoe's *Leo X.*; Sismondi's *Literature*; Ranke's *Popes.*)

LEO, *Leonardo*, one of the most distinguished composers of the Neapolitan school of music, was born at Naples in 1694. He studied for several years at Rome under the celebrated composer G. O. Pitoni, who was also the master of Feo and Durante. On his return to Naples in 1717, Leo was appointed chapel-master of the church Santa Maria Solitaria, and afterwards became master of the conservatory La Pietà, and finally of the conservatory of Sant' Onofrio, in which last school several of the greatest composers of the eighteenth century were his pupils. Some writers have stated that he died in the year 1742, but the Abate Giuseppe Bertini, in his *Dizionario Storico*, &c., 1814, says that Leo died in 1745. A later writer refers to the inscription on a portrait of Leo, preserved in the Royal College of Music at Naples, according to which Leo's death occurred in 1756. He died of apoplexy, and was found dead with his head leaning on his harpsichord. Alessandro Scarlatti, and his successors Durante, Leo, and Feo, share the honour of having founded the great Neapolitan school of musical composition. Leo was a voluminous composer for the church and for the theatre, and his music is always beautiful and expressive, as well as original and scientific. Dr Burney speaks highly of Leo's music, and alludes to the *Miserere* in eight real parts, which was performed by more than forty voices at the Pantheon, London, in 1781. That *Miserere*, for two choirs without orchestra, was published at Paris, by Choron, in 1808.

(G. F. G.)

LEOBEN, a town of Austria, in Styria, in the circle and 9 miles W.S.W. of Bruck, on the River Mur, 1670 feet above the sea-level; N. Lat. 47. 23. 36, E. Long. 15. 0. 25.

It is surrounded by a wall with three gates, and has extensive barracks, and several elegant public buildings, as the town-house, deanery church, and theatre. Some trade is carried on, principally in coal, iron, and salt. A treaty of peace was signed here between France and Austria on the 18th of April 1797. Pop. 2500.

LEOCHARES, an Athenian sculptor, is mentioned by Pliny as living B.C. 372. In B.C. 352, he was one of those employed to erect the famous mausoleum in honour of Mausolus, King of Caria. He was engaged, along with other artists, in commemorating Philip's victory at Chæro-neia, B.C. 338, and produced, for that purpose, his famous portrait statues of Philip, Alexander, Amyntas, Olympias, and Eurydice. The time of his death is unknown. His masterpiece was the Rape of Ganymede, by the bird of Jove, a bronze statue, which was much admired in its own time; and though now known only through very imperfect marble copies, still charms by its blended grace and dignity. The best copy is in the Museo Pio-Clementino. Of his other statues, the most famous are his Jupiter Tonans, characterized by Pliny as "*ante cuncta laudabilem*," and his Autolycus.

LEOMINSTER, a municipal and parliamentary borough and market-town of England, county of Hereford, on the Lugg, a tributary of the Wye, 12 miles N. by W. of Hereford, and 137 miles W.N.W. of London. The town-hall, or "butter cross," is a quaint-looking structure of wood and plaster, erected about two centuries ago. The parish church is a handsome edifice, exhibiting the architecture of various periods, and surmounted by a tower 100 feet high. A free grammar school, founded by Queen Mary, has ceased to furnish gratuitous instruction, and is now a private school. Leominster has a considerable trade in wheat, hops, cider, and wool; and some manufactures of woollens, leather, hats, and gloves, for which last it was once noted. The borough is governed by a mayor, 4 aldermen, and 12 councillors, and returns 2 members to parliament. Registered electors 551. Pop. (1851) 5214.

LEON, one of the old kingdoms of Spain, lying between N. Lat. 40. 10. and 43., W. Long. 4. and 7., and divided into the modern provinces of Leon, Zamora, and Salamanca. It is bounded by Asturias on the N., Old Castile on the E., Estremadura on the S., and Galicia and Portugal on the W.; area 15,027 square miles. The whole region is included in the basin of the Douro, with the exception of a small portion at the N.W. angle, which is drained by the Sil, an affluent of the Minho. Leon is inclosed by the two great mountain ranges that pass along its northern and southern frontiers. The Asturian Mountains on the N. form part of the great Pyrenean chain, and send off various offshoots into Leon, especially one great chain extending in a S. and S.W. direction through the northern part of the province, and separating the basin of the Douro from that of the Minho. The southern range forms part of the great central chain of the peninsula, and the highest of its summits, the Sierra de Gredos, rises to the height of 10,552 feet. There is a small range which leaves the southern chain, and runs N.W. across the southern part of the province. From these hilly regions flow down a considerable portion of what constitutes the volume of the Douro, including the Esla, with its tributaries, from the mountains of Asturias, and the Tormes from the southern range. Iron is the chief mineralogical production, and is manufactured in various ways. The soil is good, but much in want of irrigation. The mountainous parts of the province are richly wooded, and its oaks are reputed the best in Spain. The plains are very fertile, and produce abundant crops of wheat, maize, flax, &c., though the agriculture is very imperfect. The inhabitants are chiefly employed in tending sheep and cattle. The mules and asses of the province are celebrated throughout Spain.

Leochares
||
Leon.

Leon.

The Leonese are a hardy set of people, inured to mountain life, and jealous of any innovation that comes from the plains. They are ill-housed, ill-educated, and ill-fed. Industry is altogether in a wretched state, and consequently there is very little trade. The means of communication are few and bad, the roads being in a barely passable condition. Pop. (1849) 708,833.

Leon was anciently inhabited by the Vettones and Cal-laici, and formed part of *Hispania Tarraconensis*. In the eighth century it was consolidated into a kingdom by Don Pelayo and his successors, and in the eleventh incorporated with the kingdom of Castile by Ferdinand the Great. After some fruitless attempts to regain its independence, it was finally subjugated in the thirteenth century by Ferdinand III.

The modern province of Leon comprises the northern part of the old province, and is bounded on the N. by Asturias, E. by Old Castile, S. by Valladolid and Zamora, and W. by Galicia. Its greatest length is 120 miles, and its mean breadth 60 miles. The surface is hilly, and generally affords good pasturage for cattle, and it is traversed by a number of streams, of which the most considerable are Upper Douro, the Esla, and Sil. Area 5871 square miles. Pop. in 1849, 288,833.

LEON (the ancient *Legio*, so called from the *Legio septima Gemina* having been stationed here), a city of Spain, capital of the above province, situate in the angle formed by the junction of the Torio and Bernesga, 176 miles N.W. of Madrid, in N. Lat. 42. 30.; W. Long. 5. 35. The town is surrounded by old decayed walls, and though containing many magnificent buildings, presents everywhere the appearance of ruin and decay. The streets are narrow and dirty, conveying the idea of great poverty. Some of the edifices are exceedingly handsome. The cathedral, founded about 1199, was formerly one of the most graceful and elegant buildings in the world. It is built in the pointed Gothic style, of a warm cream-coloured stone, and is remarkable for its lightness and proportion. The grand west entrance from the *Plaza Mayor* has three portals, richly ornamented with elaborate sculpture, a noble rose window, surmounted by a pinnacle, and a tower on each side. The south front has also a *plaza* and three arched doorways, richly sculptured. The north façade has been deformed by balustrades and candelabra; the east is circular and Gothic, with flying buttresses and pinnacles. The interior is also remarkable for its lightness and simplicity, but has been greatly deteriorated by modern attempts at improvement. It contains much carved work, and many monuments and relics of interest. Most notable among the other buildings are,—the church of San Isidoro, a huge structure, also Gothic, founded in 1063; the convent of San Marcos de Leon, once the property of the order of Santiago; the town-house, built in 1585; the episcopal palace; public library, contained in an old nunnery; and a palace called *La Casa de los Guzmanes*. There are many institutions for educational and benevolent purposes, including a diocesan seminary; the gymnasium; primary, normal, and other schools; and four hospitals. Weaving linens, knitting caps and stockings, and making gloves, are the principal occupations of the people. What trade there is is mainly owing to two weekly markets and three annual fairs, which last for several days.

Leon was founded prior to the reign of the Emperor Galba, and was taken by Leovigildo in A.D. 586. On being recovered from the Moors, who held it for some time, it became for three centuries the residence of the kings of Leon. Under Don Pedro it lost this honour, by the transference of the court to Seville. It was sacked by Soult in December 1808. Remains of the ancient Roman wall are still extant. Pop. about 5500.

LEON, a town of Central America, capital of Nicaragua,

VOL. XIII.

in N. Lat. 12. 25., W. Long. 86. 50.; 90 miles N.W. of Leon, Isla Grenada, and 10 from the Pacific Ocean. The town is laid out on a regular plan, with spacious streets and squares, and occupies a large space. The houses are chiefly built of unbaked bricks, and seldom higher than one storey. Its public buildings are among the most beautiful in Central America. Pre-eminent stands the cathedral, with a lofty dome and two towers with pyramidal tops; it has the appearance of a fortress, and was at one time surmounted by thirty guns: there are on its walls marks of repeated bombardments. The bishop's palace has an elegant portico and fine gardens attached to it. Many of the churches are fine structures, the principal being those of La Merced, Recoleccion, and Calvario. The other most prominent buildings are the Tridentine College of St Ramon, once an important establishment, but now decayed; the government-house; and the hospital, formerly the convent of San Juan de Dios. Its suburb, Subtiaba, or Old Leon, has also some fine buildings, the chief of which is its church, consisting of three naves, with columns of cedar, and crowned by beautiful towers. Dressed leather and cutlery are the staple manufactures of Leon; its commerce is inconsiderable, and is confined to the neighbourhood. It was originally founded in 1523 on the spot now occupied by Old Leon, and was removed to its present position in 1532. The revolutions, of which the country has often been the theatre, have almost all severely visited Leon, and plenteous traces of these visitations are still to be seen. Pop. about 25,000.

LEON, *Isla de*, an island on the S.W. coast of Spain, province of Cadiz, separated from the mainland by a narrow but deep strait, called Santi Petri, is about 12 miles in length from S.E. to N.W., and from 1 to 3 miles in breadth. The broadest portion is next the mainland, while the narrowest part, which forms a long spit, juts into the Bay of Cadiz. On the extremity of this peninsula stands the city of Cadiz, cut off from the rest of the island by a fortification called La Cortadura. The surface of Isla de Leon is flat and covered with saline marshes, from which large quantities of salt are extracted by the inhabitants. Communication with the continent is effected by means of an ancient bridge thrown over the Santi Petri. The chief towns on the island are Cadiz and San Carlos.

LEON *Nuevo*, a Mexican state. See MEXICO.

LEON, PETER CIEGA DE, author of the *History of Peru*. He left Spain, his native country, at thirteen years of age, in order to proceed into America, where he resided seventeen years, and observed so many remarkable things, that he resolved to commit them to writing. His history was begun in 1541, and completed in 1550. He was at Lima, the capital of the kingdom of Peru, when he put the finishing stroke to the work, and was then thirty-two years of age. The first part was printed at Seville in 1553.

LEONFORTE, a walled town in the interior of Sicily, province of Catania, 37 miles W.N.W. of the town of that name, is situate in a mountainous district near the right bank of the Dittaino. It consists, for the most part, of a large square, with two main streets diverging therefrom. The inhabitants trade in grain, wine, oil, silk, sulphur, and asphaltum; the two last existing in large quantities in the neighbourhood. An annual fair is held here. Pop. about 11,000.

LEONINE VERSES, were Latin compositions, constructed according to the laws of the classic metres, but also elaborately decorated with rhyme. Though possessing no great merit, they were very popular in the middle ages. The name is probably derived from Leoninus, a canon of Paris, and subsequently monk at Marseilles, in the twelfth century. Other derivations have been proposed, but with little plausibility. These verses have been traced as far back as the third century, at which era Commodianus wrote a piece of 1200 jingling verses. Two centuries after this, Latin

de
Leonine
Verses.

Leopardi. rhyme appears to have been introduced into the hymns sung in the churches. (See HYMNS.) St Augustine and the venerable Bede are amongst the number of leonizers. The poem of the former against the Donatists contains 270 lines, all of which rhyme to the letter E. One of the most popular works of the eleventh century, *Regimen Sanitatis Salernitanum*, which proceeded from the physicians of Salerno, belongs to the same school. The history of the first Crusade, and the adventures of Richard Cœur de Lion, were celebrated in similar strains.

The proper leonine consists of a couplet rhyming at the end. But the line or two lines may have the rhyme distributed throughout in a great variety of ways. When the verse is divided into two members, each member, not only of the line, but of the couplet, may rhyme. Or, as in the following, the corresponding pauses in the couplet may rhyme:—

“ Si tibi grata *seges*—est morum, gratus *haberis*;
Si virtutis *eges*—despiciendus *eris*.”

But the greatest amount of variety was produced by dividing the verse into three pauses, *e.g.*—

“ O miseratrix—O dominatrix—præcipe dictu;
Ne devastemur—ne lapidemur—grandinis ictu.”

Sometimes the three members rhymed—sometimes the whole verse of the couplet; and even farther than this, leonines occur in which every word of the one line rhymes to every word in the second. As in the case when the line was divided into two members, so here the rhyme might be manifested in the corresponding pauses of the couplet. Another device of the leonizers was that of making a pause supply the place of a common introduction to a number of lines following. Thus, in the rules to be observed at meals,—

“ Dum manducatis { vultus hilares habeatis;
sal cultello capiat; }
quid edendum sit ne petatis, &c. ;”

and so on for eleven lines, each ending in *atis*. The vigorous literature which arose at the time of the Reformation almost entirely banished the taste for leonizing.

LEOPARDI (GIACOMO), COUNT, eldest son of the Count Monaldo Leopardi and the Marchioness Adelaide Artici, was born at Recanati, in the march of Ancona, June 29, 1798. In early childhood he was taught Latin and the grammar of his own language by two priests; and in his tenth year he began, without assistance, the study of Greek. Until his fourteenth year, he had no other instructor than the extensive library which his father, himself a literary man, had inherited from his ancestors.

The first part of his short career was entirely devoted to philology, in which his attainments were so great as to secure him a place among the most eminent philologists of his day, at an age when most men are still studying at college. In August 1814, when just sixteen years of age, he completed his commentary on *Porphyry's Life of Plotinus*, from which Creuzer has extracted the addenda, to be found in the third volume. In the same year, Leopardi wrote his commentaries—*Sulla vita e gli scritti di taluni retori del II. secolo*, a book of such merit, that, when Cardinal Mai published an edition of Fronto's *Letters*, in the following year, he availed himself of Leopardi's annotations; and not long after, when editing *Dionysius of Halicarnassus*, he quoted his letter to Giordani as an authority. Leopardi's next work, *Saggio sugli errori Popolari degli Antichi*, published in 1815, astonished the learned by the variety and amount of erudition displayed by a youth of seventeen. De Sinner, in his *Excerpta ex schedis criticis Jacobi Leopardi Comitissæ*, Bonnæ, 1834, lauds the “*admirandæ lectionis et eruditionis opus*.” Another essay, *Sulla riputazione di Orazio fra gli Antichi*, which appeared in 1816, shows how deeply he was imbued with the feelings of the ancients. The *Osservazioni sulla Batrachomachia* (1817) were reprinted by the learned

Bothe, in his celebrated edition of Homer's *Odyssey* (Leipsic, 1834), and by Berger de Xivrey, in his second edition of the *Batrachomachia* (1837). The *Annotazioni alla Cronaca di Eusebio*, published by Mai and Zorhab, the dissertation on Moschus and Bion, the translation of their *Idyls*, and a number of valuable researches, remarks, and essays, on other Greek and Latin authors, followed each other in rapid succession during the years 1816–17.

Leopardi's knowledge of the dead languages, added to his own fine intellect and quick perception, enabled him so to identify himself with the ancient world, that his *Hymn to Neptune*, which he gave as a translation of a newly-discovered Greek poem, and two Greek odes, which he passed off as Odes by Anacreon, published in 1817, remained for some time undetected forgeries. Another forgery (in 1826), the translation of a *Martyrdom of the Holy Fathers of Mount Sinai*, was accepted by Cesari, and admired as a *testo di lingua*. A dissertation on the *Titanomachia*, from the *Theogony* of Hesiod, and some very fine translations from Simonides, terminated the first epoch of his life.

From his constant researches into the social, political, and heroic elements of antiquity, he had acquired an enthusiastic elevation of character, which, added to his retired life and his simplicity of manners, seemed to remove him entirely from his own age, and to connect him with the great men of ancient Greece and Rome. Thus inspired by the noble deeds, and tempered by the severe beauty of his models, his poetry burst forth with a pathos and energy that has led an enthusiastic critic to affirm, that Italian poetry began with Dante and ended with Leopardi. His first *canzone* was dedicated to Italy, his second to Dante, his third to Cardinal Mai. With the political feeling common to all the modern poets of Italy, there breathes in Leopardi's verses a spirit of sublime scorn, such as an ancient Roman might be supposed to feel when writing to an audience of his degenerate countrymen.

At the age of twenty, he had a reputation throughout Italy for the finish of his style, the vigour of his sentiments, and the Attic elegance of his versification. He was then at the zenith of his fame. A year before, he had said, in a letter to one of his friends,—“I do not wish to live with the multitude: mediocrity frightens me.” But the precocious genius already carried within him the germs of disease and death. He was soon after assailed by a severe illness, and, in 1819, his sight was so much impaired, that he was forbidden to read; and an affection of the spine brought with it acute pain and deformity. He was then, for the first time, compelled to leave his home at Recanati. The snows of the Apennines made his residence there injurious; while political disagreement between him and his father added mental to physical suffering. He went to Rome, where he became acquainted with Niebuhr, who spoke and wrote so highly of him, that the Chevalier Bunsen, when in that city, went to visit him, and was surprised to find the philologist and poet in a poor chamber, “pale and shy, a mere youth, of weakly figure, and obviously in bad health.” Niebuhr offered him a professorship in the University of Berlin, but this he declined. Bunsen remained his warm admirer to the last. At this period, he contributed to the *Effemeridi Letterarie di Roma* his annotations on the Armenian *Philo* of Aucher, a translation of Virgil's *Moretum*, and some learned papers on Cicero's *De Republica*; at the same time, he was intrusted with the arrangement of the Greek manuscripts in the *Bibliotheca Barberiniana*.

It was now that he fell into that desponding state of mind which casts a peculiarly mournful shadow over his poetry. The contrast between the great men of antiquity with whom, in his library at home, he may be said to have lived, and the meanness of those with whom he now mingled in daily life, swept away the bright illusions of his youth, and made him feel a stranger in the world. To the political, social,

Lepanto. and religious misfortunes of his country, which affected him deeply, there were added personal difficulties and struggles, which made his life a burden. He travelled from Rome to Milan, thence to Florence and Bologna, and then returned to Rome again; but his moral illness seemed even more incurable than that of his body, and nothing could overcome his growing disgust of life. Amid his misfortunes he met with one consolation, the friendship of Antonio Ranieri, a Neapolitan, who invited him to his house at Naples, where he remained seven years. While there, Leopardi passed his time alternately at the foot of Vesuvius, where he uttered the last and most plaintive of his songs, *La Ginestra, o il Fiore de' Deserti*, and on the Hill of Capodimonte, where he died of dropsy, 16th June 1837.

As a philologist Leopardi belongs to that class of patient investigators who have thrown that light of sound criticism on classic literature by which Germany has so justly acquired her learned reputation. The Italians, however, to whom Europe is indebted for the preservation of the treasures of ancient culture, have not, in the midst of adverse circumstances, forgotten the traditions of their ancestors, and the Niebuhrs, Creuzers, Bothes, Theils, &c., find their rivals in the Marinis, Mais, Giordanis, Cancellieris, &c., to whom we must now add the name of Leopardi. As a poet, Leopardi has written some of the most painfully eloquent passages to be found in any language. His passion is spontaneous, deep, and true—never exceeding the modesty of nature. He stands almost alone between Alfieri, Parini, and Foscolo, on one side, and Monti and Manzoni, on the other. The *Paralipomei della Batrachiomachia* exhibit a fair example of his power of satire; in this style of composition he is neither so delicate as Parini, nor so original as Giusti; yet he is more impassioned than the one, and more correct than the other. He is, however, more a Lucian than a Juvenal. Among his poems may be found some charming sketches from nature, calm, delicate, and highly finished. Such are *Il Sabato del Villaggio*, *La sera del dì di Festa*, &c. As to his prose, when his *Opere Morali*, *Detti Memorabili di F. Ottonieri*, and his *Dialoghi* appeared in 1827, Manzoni exclaimed, "This is the best written prose that has appeared for many years."

Leopardi's friend, Ranieri, erected in the little church of St Vitale, in Naples, near the Grotte di Posilippo, not far from the last resting-place of Virgil and Sannazzaro, a tomb of marble to his memory. The whole of his works have been translated into German by Karl L. Kannegiesser, while another translation of a part of them was published by Bothe, the learned editor of Homer. (See *Opere di Leopardi raccolte ed ordinate per cura di Ranieri, Giordani, Pellegrini e Viani, Firenze*, 1845, which is the last and most complete edition in Italian; *Sainte Beuve, Portraits Contemporaines*, vol. iii., Paris, 1846; *De Montlaur G. Leopardi*, Moulins, 1846; *Reinische's Museum*, Bonn, 1834; *Schulz* in the *Italia*, a German selection of various writers, Rome, 1840; *Blessig-Augsburger Allgemeine Zeitung*, 1840; and the *Quarterly Review*, London, 1849–50, vol. lxxxvi. (E. F.)

LEPANTO, the ancient *Naupactus*, called by the Greek peasants *Epakto*, a town of Northern Greece, province of Etolia, situate on the River Morneo, about 4 miles E.N.E. from the Castle of Roumelia, in N. Lat. 38. 21. 50., and E. Long. 21. 46. It stands in the midst of a fertile territory, covered with olives, vineyards, and corn fields. Viewed from the sea, it is of a triangular form, receding up the slope of a hill, crowned by a fortress, from which a wall, diverging on either side, runs down to the shore, and shuts it in. Several walls run across the inclosure, with gates for intercommunication. The modern town is confined to the lowest inclosure, in which is also the harbour, which, although once available for ships of great size, is now navigable only by small craft.

The name *Naupactus* is said to have originated with the Heraclidæ, who are reported to have built there the fleet with which they invaded the Peloponnesus. After the Persian war it fell into the possession of the Athenians, who settled in it the expatriated Messenians. The Athenians made it their chief military station in Western Greece during the Peloponnesian war. At its close, Lepanto was taken by the Locrians, and afterwards passed in succession through the hands of the Etolians, Macedonians, Achæans, and Romans. In 1475 it was invested by the Turks, who, after the loss of 30,000 men in four months, were forced to raise the siege. Within the Gulf of Lepanto, in 1571, was fought the great naval engagement between the Ottomans and the Christian powers of the Mediterranean, under Don Juan of Austria, in which the former lost about 200 galleys, and 20,000 men. Cervantes, the author of *Don Quixote*, distinguished himself in this conflict.

LEPIDI, a Roman family, one of the most distinguished of the Æmilian clan, whose names frequently occur in Roman history.

Marcus Æmilius Lepidus, was one of the three Roman ambassadors sent to the Egyptian court in 201 B.C., became one of the pontiffs in 199, was elected ædile in 192, prætor in 191, and consul in 187. In 180 B.C. he was created pontifex maximus, in 179 censor, and in 175 elected consul a second time. After having been six times appointed *princeps senatus*, he died in 152 B.C.

Marcus Æmilius Lepidus Porcina, becoming consul in 137 B.C., waged war with the Vaccæi in Spain, without the sanction of the senate, and for this offence was degraded from his proconsulship in 136 B.C. He was augur in 125 B.C.

Marcus Æmilius Lepidus, father of the triumvir, was prætor in Sicily in 81 B.C. In 79 B.C. he was the rival of Sulla for the consulship, and through the influence of Pompey was successful. Having raised an army for the purpose of overthrowing the aristocratic constitution established by Sulla, he was declared a public enemy by the senate in 77 B.C., and having been defeated and driven from Italy, he died shortly afterwards of a broken heart.

Lucius Æmilius Paulus, son of the preceding, accused Catiline in 63 B.C., was quæstor in Macedonia in 59 B.C., and endeavoured to effect the recall of Cicero from banishment in 57 B.C. He was ædile in 55 B.C., and prætor in 53 B.C. Becoming consul in 50 B.C., he opposed the ambitious designs of Cæsar, but a bribe from the latter changed his conduct. In 43 B.C., along with others of the senators, he declared his brother, the triumvir, a public enemy. He died soon afterwards.

Marcus Æmilius Lepidus, the triumvir, was appointed interrex in 52 B.C., for the purpose of holding the comitia. At the commencement of the civil war in 49 B.C., he espoused the cause of Cæsar, who appointed him, in 48 B.C., proconsul of Hispania Citerior, and in 46 B.C. named him his colleague in the consulship. In 43 B.C., in concert with Octavian and Anthony, he formed the first triumvirate, which was renewed in 37 B.C., and dissolved in 36 B.C. by Lepidus being deprived of all power, and sent into private life. He died in 13 B.C.

Paulus Æmilius Lepidus, the son of L. Æmilius Paulus, and nephew of the triumvir, became consul in 34 B.C., and censor in 22 B.C., and died while holding the latter office.

LEPROSY, a chronic cutaneous tubercular disease, prevalent from the earliest historical times, among the ancient Jews and Egyptians, and a malady that was very common during the middle ages in the different kingdoms of Europe, and which still exists to a great extent in many quarters of the old and new world. Leprosy is one of the most incurable and most loathsome of human maladies. When speaking of the cases of it which he saw in Syria, in the seventeenth century, the old English traveller Maundrell describes it as a "distemper so

Lepidi
Leprosy.

Leprosy.

noisome that it might well pass for the utmost corruption of the human body on this side the grave." In many medical works, from the time of Aretæus, Ætius, and the later school of Greek physicians, down to our own days, the affection is described under the name of elephantiasis, or elephant disease, because, to quote the words of Aretæus, "It is disgusting to the sight, and terrible in all respects (*et visu fœdus et in omnibus terribilis*), like the beast of the same name."

When leprosy, or the elephantiasis of the Greek physicians, is fully developed, it is characterized by the presence of dusky red, or livid tubercles of different sizes upon the face, lips, nose, eye-brows, ears, and extremities of the body. The skin of the tuberculated face is at the same time thickened, wrinkled, and shining, and the features very greatly distorted. The hair of the eye-brows, eyelashes, and beard falls off; the eyes are often injected, and the conjunctiva swelled; the voice becomes hoarse and nasal; the sense of smell is impaired or lost; and that of touch, or common sensation, is strangely altered, for, whilst the tuberculated and other affected parts are, in the first instance, sometimes supersensitive, latterly, in the course of the disease, they become paralyzed or anæsthetic. As the malady proceeds onwards in its course, the tubercles soften and open; ulcerations of similar mucous tubercles appear in the nose and throat, rendering the breath extremely offensive; tubercular masses, or leprous tubercles, as shown by dissection, begin to form also internally upon various mucous membranes, and on the surface of the kidneys, lungs, &c.; cracks, fissures, and circular ulcers appear on the fingers, toes, and extremities, and joint after joint drops off by a kind of spontaneous gangrene. Sometimes the upper and sometimes the lower extremities are specially affected by this mortification and mutilation of parts. Dr Halbesk, in looking down from a neighbouring height into the large leper hospital of Hamel en Arade, tells us that he noticed particularly two of the leper inmates sowing pease in the field. "The one had no hands, the other had no feet—these members being wasted away by disease. The one who wanted the hands was carrying the other who wanted the feet upon his back, and he again carried in his hands the bag of seed, and dropped a pea every now and then, which the other pressed into the ground with his foot; and so they managed the work of one man between the two." The duration of tubercular leprosy from its first commencement to its fatal termination is usually about nine or ten years.

An endless variety of medical measures has been tried with the hope of arresting or curing tubercular leprosy with little or indeed no success. But though the disease in individual subjects seems to be beyond the power of medical control, yet the malady, as affecting individual communities and kingdoms, has sometimes been more or less completely arrested in its course and prevalence.

Leprosy still exists in Palestine and Egypt, the countries from which we have the first accounts of it. On the reputed site of the house of Naaman at Damascus, stands at the present day an hospital filled with unfortunate patients affected, like him, with leprosy. Outside the Zion gate at Jerusalem there is still a leper village, the inhabitants of which yet speak to you "afar off," as they did in the time of Christ. But the same disease is now almost unknown at the present hour in the central and western kingdoms of Europe, and yet in the middle ages it prevailed in one and all of them, to a frightful extent. Laws were enacted by almost all the princes and courts of Europe to arrest its diffusion among their subjects; the pope issued bulls with regard to the ecclesiastical separation and rights of the infected; a particular order of knighthood was instituted to watch over the sick; and leper hospitals or lazarettos were everywhere instituted to receive the victims of the disease. The number of these houses has certainly

been often erroneously stated, in consequence of a strange mistake committed by Ducange, in quoting from Matthew Paris a passage in which that historian contrasts the respective possessions belonging in the thirteenth century to the Hospitalarii, Knights Hospitallers, or Knights of St John, as they were termed, and the Knights Templars. The 19,000 lazaretto-houses in Christendom, as interpreted by Ducange, mark in Matthew Paris's work merely the number of manors or commandaries of the Hospitalarii, and have no reference whatever to leprosy or lazaretto-houses. But still, that an immense number of leper-houses existed on the Continent at the period mentioned, is abundantly shown in many of the historical documents of that age. Louis VIII. promulgated a code of laws in 1226 for the regulation of the French leper hospitals; and these hospitals were, at that date, computed to amount, in the then limited kingdom of France, to not less than 2000 in number (*deux mille leproseries*). They afterwards, as is alleged by Velley, even increased in number, so much so, that there was scarcely a town or burgh in the country that was not provided with a leper hospital. In his history of the reign of Philip II., Mezeray uses the same language in regard to the prevalence of leprosy and leprous patients in France during the twelfth century. Muratori gives a nearly similar account of the extent of the disease during the middle ages in Italy; and the old Scandinavian historians amply prove that the inhabitants of the kingdoms of Northern Europe equally became its unfortunate victims.

In England and Scotland, during the middle ages, leprosy was as rife as it was on the neighbouring continent of Europe. Almost every large town in Great Britain had a leper hospital or village near it, for the reception and separation of the diseased. Some cities were provided with more than one. There were six leper hospitals in Norwich or its immediate vicinity, and five at Lynn Regis.

The ancient leper hospitals of this and other countries were intended for the isolation of the infected, not for their cure. They were charitable, hygienic, and religious, rather than medical institutions. A few of them, indeed, were well endowed, as that of Sherburne, Maiden-Bradley, Burton lazars, and others in England, and Kingcase in Scotland; but the greater part of these institutions were supported by voluntary charity; and the principal subsistence of the inmates seems to have been derived from casual alms. By some of the old forest laws of England, game and animals found dead in the wood and fields were sent to the nearest leper hospital; and in Scotland the fish left putrid and unsold in the burgh markets, were adjudged to them. The lepers were usually, by law, restricted as to the districts and places in which they presented themselves to beg for subsistence. According to the Scottish "Burrow Lawes," it was ordained that lepers "sall not gang fra dure to dure, but sall sit at the ports of the burgh, and seek almas fra them that passes in and furth;" and the Scottish parliament of 1427 enacted, that they should not be allowed to sit and beg, "neither in kirk nor in kirk-yairde, nor other places within the burrowes, but at their owne hospital." In the leper hospital of Edinburgh, the inmates begged alternately for the general community, sitting for this purpose at the door of the hospital; but they were ordered there not to "cry or ask for alms, utherways then be thair clapper." For the inmates of this and other similar institutions in this and other countries, were usually obliged by law to warn those approaching them of the presence of an infected fellow-mortal, by using a rattle or wooden clapper; whilst, at the same time, they held in their hand a "cop," or receiving dish, into which the charitable might drop their alms.

In Great Britain, as on the Continent, those affected, or supposed to be affected, with leprosy, were obliged to seclude themselves from society, or enter a leper hospital,

Leprosy.

Leprosy. both by general custom and usage, and by direct legal enactments in regard to them, made both by the court and church. Besides, according to the tenor of various old civil codes and local enactments in this and other countries, when a person became affected with leprosy, he was considered as legally and politically dead, and lost the privileges belonging to his right of citizenship. The church also took the same view, and on the day on which he was separated from his fellow-creatures, and consigned for the remainder of life to a lazaret-house, they performed over and around the yet living sufferer the various solemn ceremonies for the burial of the dead, and the priest terminated the long and fearful formula of his separation from his living fellow-creatures, by throwing upon the body of the poor outcast a shovelful of earth, in imitation of the closure of the grave.

The ritual of the French church retained, till a very late period, the various forms, prayers, and ceremonies of social isolation and banishment, to which the leper was thus subjected on the day of his living funeral. But in France, as in most other parts of Central Europe, the ceremonial is no longer required, as the malady has entirely, or almost entirely, disappeared. Isolated cases of it still occasionally occur in some villages on the shores of the Mediterranean, near Marseilles. It has been seen also during the present century in several sea-board localities in Spain; and one of the Greek islands, at the present day, continues to form a leper hospital. In Europe, however, the disease is now principally confined to Norway; but in that small kingdom, at the last census, there were found to be upwards of 2000 of its population affected with leprosy; and more than one hospital yet exists for it in Iceland. In Great Britain, no indigenous case of the disease was seen from the end of the last century till a few years ago, when one or two cases occurred in the old haunts of the disease among the western islands of Scotland, and elsewhere; and it is quite possible that it may yet revisit us again to some extent. One or two hospitals for the reception of lepers have lately been built in Canada.

Few or no physicians at the present day hold that leprosy is a disease which spreads from the infected to the healthy by contagion. But there is ample reason for believing that the affection is often transmitted hereditarily from generation to generation. Further, there are local or endemic causes in certain parts of the world capable of producing it; as we see it sometimes attack Europeans who have been residing for a succession of years in districts in the West Indies, and other countries where the disease is prevalent. What these endemic causes or conditions are, we know not. The frequency of the malady in former times has been confidently ascribed, by different authors, to peculiarities in the diet, dress, personal and domestic habits, &c., of our forefathers; and, certainly, their mode of life was, in many respects, specially calculated to generate derangements and eruptions of the skin. The good old Saxon practice of bathing appears to have become forgotten after the date of the Norman conquest; and in the subsequent history of these early times, we might trace various indirect and direct causes of cutaneous disease, in the close hovels and unventilated dwellings of the period; in the habits of personal uncleanness; in the rough straw-bedding then generally in use, and which "hard lodging" Hollinshed describes as still used by the servants in his day, "with seldome (he adds) anie sheete vnder their bodies to keepe them from the pricking straws that run oft through the canvas, and rase their hardened hides;" and probably, also, in the articles of diet on which the general community were obliged to subsist, in times before the improvement of agriculture, and the introduction of that "schamefull intemperance," as old Boece fanatically terms it, "when na fische in the see, nor foule in the aire, nor beast in the wod, may have rest, but are socht heir and thair to satisfy the hungry appetit." For

the investigation of this and other allied questions in the history of the production of our older epidemic and endemic diseases, the works of Hollinshed, Strutt, Henry, Chalmers, Macpherson, and others, contain a great and available mass of materials. We will only, however, here pause to observe, that we believe it would be no easy matter to point out the exact differences in those physical conditions of the inhabitants of this country, in former and in modern times, which may have led to the prevalence of the disease amongst our ancestors, and to its disappearance amongst us. If poverty in diet, or personal wants, and filth and wretchedness in their deepest degrees, could generate the malady, there are certainly still numerous spots in continental Europe, and even in our own land, where, unfortunately, all these elements of disease are, in our own day, in full and active operation, without any such specific result following. The alleged causes are present without the alleged effects.

In order to obtain anything like satisfactory results of the supposed physical causes of leprosy in Europe in former times, the whole question would require to be thoroughly investigated in connection with two others,—viz., the allied physical circumstances, firstly, of the inhabitants of those countries in which the disease, in the same way, formerly raged; and, secondly, of those districts of the world in which it is still prevalent. It is only by following such a line of inquiry that we could hope, if at all, to separate mere matters of opinion from matters of fact, and at last to obtain, by a kind of reasoning by exclusion, the exact physical condition or conditions of a people that are capable of originating or of spreading this particular species of disease. The difficulty of the problem may be easily appreciated by glancing for a moment at the diversified geographical localities and circumstances under which the tubercular leprosy is known at the present day to prevail. In modern times it has been found existing, to a more or less limited extent, in places the most distant and dissimilar in regard to temperature, climate, situation, soil, &c., as in Sumatra, under the equator, and in parts of Iceland almost within the verge of the arctic circle; in the temperate regions of both hemispheres, as (in the southern) at Hamel en Arade, in the Cape district, and (in the northern) at Madeira and Morocco; in the dry and arid plains of Arabia, and in the wet and malarious districts of Batavia and Surinam; along the shores of Guiana and Sierra Leone, and in the interior of Africa, Hindostan, Asia Minor, and Asiatic Russia; on the sea-coast, as at Carthage; and thousands of feet above the level of the ocean, as on the table-land of Mexico; on some of the islands in the Indian, Chinese, Caribbean, and Mediterranean seas; and at many sites far in the interior of the continents of Asia, Africa, and America. (J. R. S.)

LERIDA (the ancient *Ilerda*), a town of Spain, province of Catalonia, situate partly on a hill, and partly on the adjoining plain on the right bank of the Segre, here crossed by a handsome stone bridge, 85 miles W. of Barcelona. It occupies a position of great natural strength, and was in ancient times an important military station. In the Punic wars it took part with the Carthaginians, and suffered much from the Roman arms. In its immediate neighbourhood, Hanno was defeated by Scipio, B.C. 216; and it afterwards became still more famous as the scene of Cæsar's arduous campaign against Pompey's lieutenants, Afranius and Petreius, in the first year of the civil war (B.C. 49). Under the empire it was a very flourishing city, and a *municipium*, but it subsequently fell into decay. In the middle ages it again rose into importance, and in modern times it has sustained numerous sieges. It was taken by storm in 1707, during the war of the succession, and was again taken by the French in 1810. Lerida is the second city of Catalonia, and is strongly fortified. The principal street is nearly a mile in length, and consists of one long line of white houses, with red and green balconies, but the rest

Lerida.

Lerins
||
Lesbos.

of the town is generally crowded and ill built. The old cathedral presents some beautiful Gothic, with other styles. It was built by James I. of Aragon, but often repaired. It is now fast going to decay, having never been used for religious purposes since 1707, when the French made it a fortress. The new cathedral, built in the reign of Fernando VI., is an imposing structure, of Corinthian architecture, surmounted by two handsome square towers. Pop. 12,472.

LERINS, two small islands in the Mediterranean, off the coast of France, about $2\frac{1}{2}$ miles from the shore at Cannes, and belonging to the department of Var. The larger one, called Ste Marguerite, is well wooded, and is defended by a fort which for many years was the prison of the mysterious "Man of the Iron Mask." The other islet, called St Honorat, contains the remains of a fortified convent. The former was the *Leron*, and the latter the *Lerina* of the Romans.

LEROS, or LERO, a small island of the Grecian Archipelago, belonging to Turkey; situate off the W. coast of Anatolia, opposite the Gulf of Mandelyah, N. Lat. 37. 10, and E. Long. 26. 50. It is irregular in shape, and mountainous, about 9 miles in length from S.E. to N.W., and from $1\frac{1}{2}$ to 4 miles broad. The valleys are very fertile, and the harbours numerous and excellent. The chief products are grain, olives, wax, honey, and wool. The town of Lero is situate on a bay on the E. side of the island. Leros was originally colonized by Milesians about 500 B.C., and continued under the government of Miletus until that city fell into the hands of the Romans. The goddess Artemis Parthenos had a temple here, the site of which is said to be now occupied by a convent which bears her name. Pop. about 2000.

LERWICK, a seaport town, capital of the Shetland Islands, is situate on Bressay Sound, on the E. side of the mainland. It has a very irregular appearance, consisting chiefly of a number of rather poorly built houses, of from two to three storeys in height, disposed along the winding margin of the bay. Considerable improvements have, however, been recently made, and it now contains many good shops and substantial dwelling-houses. The only public buildings are the parish church, a free church, and two dissenting chapels. The fort was built in 1665 to protect the fisheries, and repaired in 1781, when it was named Fort Charlotte. Its bastions have 12 embrasures; and it is now in charge of one or two artillerymen. It has no manufactures of any extent. The harbour is very spacious, and is entirely landlocked by Bressay Island. The import and export trade is considerable. The number of vessels registered at the port on 31st December 1855 was 52, having an aggregate burden of 1581 tons. During 1855, 162 vessels, of 19,402 tons, entered; and 143 vessels, of 18,235 tons, left the port. The chief exports are fish, butter, hides, rabbit skins, and stockings. The inhabitants are chiefly employed in the fisheries.

LESBOS (MITYLENE), in *Ancient Geography*, a large triangular island in the Ægean Sea, is situate about 7 miles from the coast of Mysia, at the mouth of the Gulf of Adramyttium, between N. Lat. 38. 58. and 39. 24. It has three chief promontories,—Argennum on the N., Malea (*Zeitoun Bouroun*) on the S.E., and Sigrium (*Sigri*) on the W. On the S.W. coast, two creeks stretching far inland form two spacious harbours,—the Portus Hieræus (*Port Hiero*), and the Euripus Pyrrhæus (*Port Caloni*). The island is in general hilly, and has three principal mountains,—Ordymnus in the W., Lepethymnus in the N., and Olympus in the S. In ancient times it was famed for its delightful climate and wholesome wines, for its agates and variegated marble. It had six principal cities,—Methymna, Mitylene, Arisba, Antissa, Eressus, and Pyrrha. Each of these constituted an independent government, and had its own distinct territories. The first two, the one on the N.

and the other on the E. shore, facing the mainland, are by far the most important in the history of the island. According to tradition, Lesbos was successively peopled by Pelasgians, Ionians, and Ælians, under their leader Lesbos, who gave his name to the island. In the Peloponnesian war, the Lesbians joined the Lacedæmonians; and as a punishment all their lands, except those of Methymna, who had not acted in concert with the other cities, were seized by the Athenians. Soon after the battle of Pharsalia, it became a Roman province. It was the birthplace of the musicians Terpander and Arion, and the philosophers Pittacus and Cratippus. Its chief glory, however was derived from the lyric poetry of Alcæus and Sappho.

LESINA, an island in the Adriatic, belonging to the circle of Spalatro in Dalmatia, separated from the peninsula of Sabbioncello by the Straits of Narenta. It is about 40 miles long, by from 2 to 6 broad, chiefly mountainous, but containing, especially on the N. side, a considerable area of fertile arable land. Its climate is remarkably mild; and it produces wine and oil, figs, almonds, and other fruits. Corn is also grown, though the quantity is insufficient for the consumption of the inhabitants. It has considerable numbers of sheep, and an anchovy fishery of some importance. Pop. 12,000. The town of Lesina, situate on the S.W. coast of the island, is the see of a bishop, and seat of a court of justice. Pop. about 2000.

LESLEY, JOHN, Bishop of Ross, was born on the 29th of September 1527. In an account of his life, for which he must himself have supplied the materials, he is said to have been born of honourable parents. Knox has clearly stated that he was the son of a priest; and the illegitimacy of his birth is sufficiently ascertained from a dispensation rendering him capable of receiving holy orders. Keith conjectures, with great probability, that he was the son of Gavin Lesley, rector of Kingusie, and likewise, as he supposes, official of that diocese.

Lesley prosecuted his studies in King's College, Aberdeen, where he took the degree of A.M. In the twentieth year of his age he became a canon of the cathedral churches of Aberdeen and Elgin. Having afterwards studied at Paris, Poitiers, and Toulouse, he returned to his native country in April 1554, and was soon after appointed professor of the canon law in the University of Aberdeen.

The progress of Protestantism, however, soon disturbed his peace; and in Knox's history we have an account of a conference between selected champions on either side, in which Lesley is described as making a sorry figure. Lesley's version is, however, somewhat different, and it is even affirmed that he and his associates were imprisoned in Edinburgh. On the death of Francis the Second, Lesley was despatched to France by the Earls of Huntley, Crawford, Athole, Sutherland, and Caithness, the Archbishop of St Andrews, the Bishops of Aberdeen, Moray, and Ross, with the view of enlisting Mary in their cause. He attended the queen on her return to Scotland, and was soon after admitted an ordinary judge of the Court of Session, along with a preference to the abbacy of Lindores, and the bishopric of Ross.

To the fortunes of the queen Lesley adhered with unshaken fidelity; and he is supposed to have been the individual who suggested an expedient for granting to the Earl of Bothwell an indirect pardon for the murder of the king; a crime to which there is the strongest moral evidence that the queen was an accessory, before as well as after the fact. On her escape from Lochleven she sent for him; but the battle of Langside crushed her hopes; and it was not till the following September that he visited her at Bolton Castle, and afterwards bore an important part in the negotiations between her and Elizabeth.

Lesina

Lesley,
John.

Lesley,
John.

The scheme of a marriage between Mary and the Duke of Norfolk involved many of their adherents in danger and difficulties. Lesley was repeatedly examined before the English queen and council, and was confronted with the Earl of Leicester, who had likewise been implicated in the same transaction. Under suspicion of being accessory to the rising of the Earls of Northumberland and Westmoreland, he was placed under arrest, and was detained in custody for six weeks before he was subjected to any examination. Fresh evidence of his complicity in other transactions equally obnoxious soon after came to light, and after a long course of sickness and misfortune he was sent to the Tower, where he was subjected to the most needless cruelty, as well as harassed by the most inquisitorial investigations.

The condemnation of the Duke of Norfolk brought Lesley into fresh troubles. Of all the most material charges the proof seems in a great measure to have rested on what are described as the bishop's confessions, that is, the answers emitted during his repeated examinations after he had himself been taken into custody. On perceiving that their designs were discovered, Lesley had become more communicative, and had thus contributed to the ruin of a man whom he had so much contributed to entangle in dangerous schemes of ambition. While he was beset with such perils in England, the Regent sent Nicholas Elphinstone with a demand that he should be conveyed to Scotland; but the Duke of Montmorency brought instructions from France to intercede for his release; and this application was so far successful as to procure his removal to Farnham Castle, the seat of the Bishop of Winchester. During his confinement in the Tower, he had sought for consolation in study and meditation. There he had composed his *Piæ Consolationes*; and he was now permitted to transmit them to the queen, who devoted some of her prison hours to the task of translating a portion of it into French verse. He was induced to prepare a similar work, *Animi tranquilli Munimentum*, which he sent her in October 1573. In the meantime, he was not free from the apprehension of personal danger; the Earl of Morton having twice sent a diplomatic agent, Captain Cockburn, for the purpose of renewing the demand for the delivery of his person. Having some reliance upon his own eloquence, he now addressed to Elizabeth a Latin oration for the recovery of his liberty; and, whatever might be the effect of his classical pleading, he was soon afterwards released from his tedious confinement. The Bishop of Winchester, on receiving the necessary order, conducted him to London on 11th November. On the 16th he was brought before the council, at the house of the lord treasurer, and was informed that he would be permitted to proceed either to Scotland or France. The English statesmen seem to have been much inclined to treat him as they ultimately treated Mary herself; but although he was subjected to a long and arbitrary imprisonment, the ministers of Elizabeth never ventured to bring him to a formal trial.

In January 1574 he landed in France, where he remained till the following year, when Mary sent him on a mission to Gregory XIII., with the view of prosecuting her scheme of conveying her son to a Catholic country, and uniting him in marriage either with a daughter of the Emperor of Germany or the King of Spain. Lesley, however, was more usefully employed in preparing for the press his general history of Scotland, which was published at Rome in 1578. About this time hopes were entertained that through the influence of the Duke of Athole, the religion of Rome might regain its old footing in Scotland, and Lesley was despatched to the neighbouring coast of France to gain intelligence of any symptoms of a spreading change. He had the mishap, however, to be imprisoned by mistake at Falsburg, and he arrived in France (April

Leslie,
Charles.

1579) only to learn the death of the nobleman on whose exertions Mary and her party had built all their hopes. It was some consolation that the Cardinal de Bourbon, Archbishop of Rouen, soon afterwards appointed him suffragan and vicar-general of that diocese. In this station he continued for the space of fourteen years, and, principally for his intrepid conduct during the siege of Rouen, he was rewarded in 1594 with the bishopric of Constance, in Normandy. But from this preferment he appears to have derived no advantage; and the unhappy situation of public affairs in France induced him to seek another place of refuge. Directing his course towards Flanders, he reached Château d'Aussy, in the province of Artois, in the month of March, and afterwards proceeded to Brussels, where he experienced a friendly reception from the Archduke Ernest, governor of the Netherlands. By this prince he was rewarded with a pension of fifty crowns monthly, and the promise of a bishopric. The death of Ernest, however, frustrated this latter plan, and fast increasing sickness brought Lesley to the grave before he could reap any advantage from the favour of his successors. He died at Brussels 31st May 1596.

Of the works of Lesley we subjoin a catalogue:—

1. *A Defence of the Honour of the right highe, mightie, and noble Princesse Marie, Queene of Scotlande, and Dowager of France*, imprinted at London, 1569, 8vo. 2. *A Treatise concerning the Defence of the Honour, &c., made by Morgan Philippes, Bachelor of Divinitie*, an. 1570, Leodii, 1571, 8vo. This treatise he afterwards translated into Latin, as well as into French. 3. *Joannis Leslei Scotti, Episcopi Rossen. pro Libertate impetranda. Oratio, ad serenissimam Elizabetham Anglicæ Reginam*, Parisiis, 1574, 8vo. 4. *Joannis Leslei Scotti, Episcopi Rossen. libri duo: quorum uno, Piæ afflicti Animi Consolationes, divinaque Remedia; altero, Animi tranquilli Munimentum et Conservatio, continentur*, Parisiis, 1574, 8vo. 5. *De Origine, Moribus, et Rebus gestis Scotorum libri decem*, Romæ, 1578 and 1675, 4to. 6. *Congratulatio serenissimo Principi et illustrissimo Cardinali Alberto Archiduci Austriæ, &c., de fausto ac felici ejus Adventu ad Regimen Provinciæ Inferioris Germaniæ*, Bruxellæ, 1596, 8vo. 7. *A Discourse conteyninge a perfect Accompt given to the moste vertuous and excellent Princess, Marie Queene of Scots, and her Nobility, of his whole Charge and Proceedings during the time of his Ambassage, from his entres in England in September 1568, to the 26th of March 1572; in Anderson's Collections relating to the History of Mary Queen of Scotland*, vol. iii., Edinb. and Lond. 1727–8, 4 vols., 4to. 8. *The History of Scotland, from the death of King James I., in the year 1436, to the year 1461*, Edinb., 1830, 4to, edited by Thomas Thomson, from a MS. belonging to the Earl of Leven and Melville.

LESLIE, CHARLES, the author of a *Short and Easy Method with the Deists*, was born in 1650, in Ireland, where his father was Bishop of Raphoe, subsequently Bishop of Clogher. He graduated at Trinity College, Dublin. On his father's death, in 1671, removing to England, he enrolled as a student of law in the Temple, but soon after turned his attention to theology, and received orders in 1680. In 1687 he was appointed Chancellor of Connor, and began a long career of controversy by a debate with several popish champions, chosen for their office by Patrick Tyrrel, whom James II. had installed into the see of Clogher. His success on this occasion led him deeper into conflict with the government, and by implication with the king. Strange as it may appear, Leslie, although a bold advocate for the supremacy of law, was himself a firm believer in passive obedience; and declining at the Revolution to take the oaths of allegiance, was deprived of his benefice. In 1689 the growing commotions in Ireland induced him to remove to England, where he devoted himself to the defence of non-resistance, in several controversial pamphlets, and encountered, amongst other opponents, Burnet, Bishop of Salisbury. His incessant activity also led him into controversy with the Quakers, Jews, and Socinians. His best known work, *A Short and Easy Method with the Deists*, appeared in 1699; and in 1706, led to his being charged, somewhat paradoxically, with being vicious in argument, in such a way as to favour the progress of Popery.

Leslie,
Sir John.

In 1709 he was sent by several Jacobite gentlemen of fortune on a mission to Bar-le-duc, to convert the Pretender. That prince, however, foiled all his attempts, by forbidding him to converse about religion either with himself or with his priests. With the view of spreading Jacobite principles, Leslie addressed a letter from Bar-le-duc to a member of parliament in London, which was printed and circulated among the Jacobites in England. After the failure of the Pretender's expedition, Leslie accompanied him into Italy. Returning to England in 1721, he removed to Ireland, and died at Glaslough, Monaghan, 13th April 1722.

His principal works are,—*A View of the Times, their Principles and Practices*, London, 1750; *The Massacre of Glencoe*, London, 1703; *The Axe laid to the Root of Christianity*, London, 1706; *Querela Temporum*, London, 1695; *Theological Works*, 7 vols., Oxford, 1832, containing, among other controversial treatises, his *Short and Easy Method with the Deists*.

LESLIE, Sir John, Professor of Natural Philosophy in the University of Edinburgh, the son of a poor joiner or cabinet-maker, was born at the village of Largo, in the county of Fife, on the 16th of April 1766. In his early youth, being of feeble health, he was sent, when four years old, to a school kept by an old woman, and afterwards to a higher school. He received his first lessons in mathematics from his father and his eldest brother, and a slight knowledge of Latin at a school in the neighbouring town of Leven, which he attended for six months. The first person of any note who observed his precocious attainments, was Mr Oliphant, who became minister of Largo about the time when the boy had reached his eleventh or twelfth year. Struck with his knowledge of mathematical and physical science, he kindly lent him some scientific books; and he also strongly urged him, but without avail, to resume the study of Latin, for which he entertained at this time a strong aversion. He also became known to Professors Robinson and Stewart of Edinburgh; and by their advice he was, in his thirteenth year, sent to the University of St Andrews to study mathematics under Professor Vilant. On examination by the professor, he was found already qualified for the second or senior class; and at the close of the session he obtained a prize, and attracted the notice of the Earl of Kinnoull, then chancellor of the university, who proposed to his father to defray the expense of his son's education, on the condition that he should study for the Church. The proposal was readily embraced; and as a knowledge of Latin was now imperative, he commenced doggedly to study it, and, by the aid of a private teacher, qualified himself for entering the Humanity class. He also seems to have got rid of his strong dislike to the language; for no trace of it remained in his after life, and he is extremely fond of introducing classical quotations in his writings. His continued success during his second session secured the continued patronage of the chancellor, who invited him to Dupplin Castle. About the same time began his acquaintance with Playfair and Dr Small.

In 1783 or 1784, he quitted St Andrews, and, along with his fellow-student, James Ivory, proceeded to Edinburgh, where, though he formally entered the Divinity Hall, he contrived to devote his first session to the sciences, particularly to chemistry. In fact, he seems early to have relinquished all thoughts of the Church: a resolution, perhaps, hastened by the death of his patron, the Earl of Kinnoull, soon after his removal to Edinburgh. He continued to study here till the close of the session of 1787; and, as is customary with students of his limited means, devoted part of his time to private tuition. Acting as tutor to a young man nearly related to Adam Smith, he thus became known to that philosopher, who treated him kindly, and occasionally favoured him with directions as to his own pursuits. His first essay, "On the Resolution of Indeterminate Problems,"

composed about this time, was read to the Royal Society of Edinburgh by Mr Playfair, in 1788, and published in their *Transactions* for 1790.

In 1788 he accompanied, in the capacity of tutor, two young students of the name of Randolph, to Virginia. Here his agreeable and profitable sojourn was brought to an end, after the lapse of little more than a year, by the death of the father of his young friends; and after visiting New York and Philadelphia, he returned to his native place towards the close of the year 1789.

From some letters to his family, written about the time of his leaving America, he seems to have meditated trying his fortune in India, probably as a civil engineer; a notion that recurred afterwards without leading to any results. In January 1790, carrying, among other letters of recommendation, one from Adam Smith, he repaired to London, chiefly for the purpose of ascertaining what success he might expect from a course of lectures on natural philosophy; and the information he received soon satisfied him, as he says in a letter to one of his brothers, that "rational lectures would not succeed." He therefore employed himself for some time in writing for the *Monthly Review*, and in executing literary jobs delegated to him by his countryman, Dr William Thomson, author of the continuation of Watson's *History of Philip the Third*. In April 1790, he became tutor to his former fellow-students, the younger Wedgewoods of Etruria, in Staffordshire, where he remained till the close of 1792, in the enjoyment of a liberal salary, and of society at once agreeable and intelligent. He was at the same time assiduously employed in experimental investigations, and in completing a translation of Buffon's *Natural History of Birds*, which he had previously undertaken for a London bookseller. It was published in 1793, in 9 vols. 8vo. Though executed with fidelity and vigour, it was valued by himself in after life solely for having, by the sum which it procured him, laid the foundation of that pecuniary competency which his industrious and prudent habits soon enabled him, in a moderate degree, to attain.

In 1794, after a sojourn of some months in Holland, during which he acquired the German language, he returned to Largo. Here he remained for about two years, devoted to experimental researches, in the course of which he invented and perfected his Differential Thermometer: a contrivance suggested during his attempts to construct an accurate Hygrometer, and the parent, as it may be called, of his subsequent inventions,—the Hygroscope, Photometer, Pyroscope, Æthrioscope, and Atmometer. At a later period, when his name had attained a high degree of celebrity, he was accused of having plagiarized this invention, if not from Van Helmont, who died in 1644, at any rate from John Christopher Sturm, who died about sixty years later. But it is now, we believe, allowed, that this is just one of those curious cases so frequently found in the history of science, in which the inventor of a contrivance, partially anticipated by another, shows, by his skilful and fruitful employment of the disputed invention, how much he surpassed, and how little he needed the help of, him whom he is ungenerously supposed to have robbed of his legitimate honours.

In the spring of 1796, Mr Leslie accompanied his friend Mr Thomas Wedgewood on a tour through the N. of Germany and Switzerland, during which, as on all similar occasions, he was no less observant of the social, moral, and economical condition of countries he visited, than of their geological, meteorological, and physical aspects. On his return, he was probably engaged in his experimental pursuits, and divided his time chiefly between London and Largo, to which place, and to the society of his family, he ever was fondly attached. Early in the summer of 1799, he set out with an old college acquaintance on a tour through Denmark, part of Norway, and Sweden, and returned to Eng-

Sir John.

land about the end of November. In the following year appeared, in Nicholson's *Philosophical Journal*, "A Description of an Hygrometer and Photometer;" a paper "On the Absorbent Powers of the Different Earths;" and "Observations and Experiments on Light and Heat, with Remarks on the Inquiries of Dr Herschel on these objects." A series of more extended investigations, which he carried on while residing at Largo, resulted, in 1804, in the publication at London of his *Experimental Inquiry into the Nature and Propagation of Heat*; a work which may be considered as a development of his essay on *Heat and Climate*, read at two successive meetings of the Royal Society of London in 1793. The originality and boldness of the peculiar doctrines of the *Inquiry*, and the number of new and important facts disclosed by its ingenious experimental combinations, conspired to render it an object of extraordinary interest in the scientific world; and, indeed, it must ever be viewed as constituting an era in the history of that branch of physical science which forms its subject. The Royal Society of London unanimously adjudged to its author the Rumford Medal, appropriated as the reward of discoveries in that recondite province. Although paradoxical in many of its theories, defective in its arrangement, and over-ambitious in its style, this work is almost unrivalled in the entire range of physical science, for its indication of vigorous and inventive genius.

Previous to this period of his life, Leslie had twice appeared as a candidate for an academical chair; first in the University of St Andrews, afterwards in that of Glasgow, and on both occasions without success. Early in the year 1805, he became a candidate for the mathematical chair at Edinburgh, vacant through the promotion of Playfair to the chair of Natural Philosophy. His principal competitor, Dr Thomas Macknight, a man of respectable attainments, was one of the ministers of Edinburgh, and was supported by the majority of the city clergy. These, blinding perhaps their better judgment by an excessive zeal for the cause of their fellow-minister, fastened on one of Leslie's notes, in his essay on *Heat*, in which, after complimenting Hume's philosophical talent, he says, "that the unsophisticated notions of mankind are in perfect unison with the deductions of logic, and imply nothing more at bottom, in the relation of cause and effect, than a constant and invariable sequence." Alleging that the town-council were bound, according to the fundamental charter of the college, to act with the advice of the ministers in electing professors, they preferred a formal protest, accusing Leslie of having, in this note, "laid a foundation for rejecting all the argument that is derived from the works of God, in proof of His Being or Attributes." The patrons neglected their advice; and Leslie, to the great joy of all liberal minds, was, in March 1805, elected to the Mathematical chair. The case, however, was carried before the General Assembly; and after a memorable debate of two days, was dismissed, on the 23d of May, "as vexatious." When Leslie was informed of the charge, he exculpated himself in a very pointed letter, which was laid before his opponents, by stating, that his observations "referred entirely to the relation between cause and effect, considered as an object of physical examination."¹ This was a sufficient defence of his orthodoxy, and ought to have stopped the prosecution before the Assembly.

Entertaining lofty notions of the dignity and utility of his new vocation, he discharged its duties with great ardour. Though the bent of his genius lay more to physics than to pure mathematics, he had cultivated the study of geometry with kindred relish, and with an admiration, in particular, of the analytical investigations of the ancient geometers, which led to his happiest essay in that science. Of his *Course of Mathematics*, the first volume, comprising *Ele-*

ments of Geometry, Geometrical Analysis, and Plane Trigonometry, was published, in 1809, at Edinburgh, and republished in 1811, and in 1817. His own favourite portion, on *Geometrical Analysis*, has been extolled by the most unsparing critics of the first part, and was speedily translated into French and German. He reproduced it, in 1821, with considerable emendations, in the second volume of his *Mathematical Course*, which also contains the *Geometry of Curve Lines*. The want of a third volume, on *Descriptive Geometry* and the *Theory of Solids*, which was part of his original design, left his *Mathematical Course* incomplete. An abridgement of the first volume appeared in 1828, under the title of *Rudiments of Plane Geometry, including Geometrical Analysis, and Plane Trigonometry*. In connection with his mathematical works, we may here mention the profound and learned treatise, published in 1817, on the *Philosophy of Arithmetic*,—a republication, with considerable alterations and additions, of one of the numerous articles contributed by him to the *Supplement* of this Encyclopædia.

Notwithstanding the labours of the Mathematical chair, Leslie continued his experimental inquiries; and in June 1810, some experiments previously suggested in the course of his researches with his Hygrometer, led him to the discovery of that beautiful process of Artificial Congelation, by which he was enabled to produce ice, and even to freeze mercury at pleasure. This process consists in a combination of the powers of rarefaction and absorption, effected by placing a very strong absorbent under the receiver of an air-pump. Some endeavours were made, as in the case of the Differential Thermometer, to transfer the merit of this new discovery to a gentleman of the name of Nairne. The claim for him was founded on a paper published in 1777, in the *Transactions* of the Royal Society of London; from which it appeared that he was acquainted with the facts, that evaporation produces cold, and that sulphuric acid, the absorbent employed by Leslie, imbibes moisture. The best vindication of Leslie's claims is furnished by the admitted fact, that with Nairne's paper before them for a long course of years, the scientific world remained utterly ignorant of any such process till the date of Leslie's discovery; and even after his description of that process the most distinguished experimentalists of the capital failed in their trials of it, till it was performed there by himself in the ensuing summer!

In 1811 he performed the experiment in London before a meeting of some members of the Royal Society, and others. The discovery was announced in the same year, in the *Memoirs* of the French Institute; and the process itself was afterwards exhibited in presence of that body, by M. Pictet and M. Gay-Lussac. His experiments and views on this subject in 1813 he explained at considerable length in a small volume published at Edinburgh, and entitled, *A Short Account of Experiments and Instruments depending on the Relations of Air to Heat and Moisture*. Closely connected with the subject of this treatise, was an ingenious paper, published in 1818, in the *Transactions* of the Royal Society of Edinburgh, under this title: *On certain Impressions of Cold transmitted from the higher Atmosphere; with a description of an Instrument adapted to Measure them*. The Æthrioscope is the instrument here alluded to.

In the autumn of 1814, Leslie travelled through France and the Netherlands, where the ever-fresh beauty of the scenery, combined with the meeting of such men as Humboldt, Laplace, Berthollet, and Baron Zach, tended to render that short tour of six weeks more than usually agreeable.

The celebrated *Supplement* of this Encyclopædia, commenced in 1815, and completed in 1824, was greatly in-

Leslie,
Sir John.

¹ See Professor Stewart's *Short Statement*, p. 36, and *Report of the Debate in the General Assembly*, p. 16.*

Leslie,
Sir John.

debted to Leslie for his valuable contributions, and for the ever-ready counsel which his extensive and minute information could afford to its editor. He also contributed several articles to the *Edinburgh Review*, the principal of which are,—those on the *Physical and Chemical Memoirs of the Society of Arcueil*; on the *History of the Barometer*; on *Delambre's work on the Arithmetic of the Greeks*; on *Von Buch's Travels*; on *Humboldt's Physical view of the Equatorial Regions*, and on *His Travels*; and on the *Attempts to discover a North-West Passage to Asia*.

In the year 1819, on the death of Playfair, he was promoted to the chair of Natural Philosophy, a sphere more propitious to his peculiar genius. One of the first cares of his new situation was the extension of the apparatus for that greatly enlarged series of experiments which he thought necessary for the illustration of the course. This, indeed, was an object from the first to the last year of his incumbency ever present to his mind; and it was through his exertions that the means of experimental illustration, in the Natural Philosophy Class, were for the first time made worthy of the place. As a teacher both of mathematics and of natural philosophy, he wanted that sequence of ideas and perspicuity of exposition which can alone lead an undisciplined intellect through complicated doctrines, and thus attain the highest success in tuition. Still, his numerous experiments, the celebrity of his name, and his well-known extraordinary powers, concurred, with great simplicity and affability of manner, to secure the respect of his students, and to sustain the fame of the University. In 1823 he published, chiefly for the use of his class, his *Elements of Natural Philosophy*; being the first volume of a course intended to extend to three, and to exhibit a comprehensive view of the principles of that congeries of sciences which we are accustomed to class under the above term. A second edition of this volume, the only part of the plan ever completed was published in 1829, with corrections and additions.

In the summer of 1823, he accomplished his long-cherished design of visiting Italy, and especially Rome; but these objects of his tour appear to have disappointed his expectations. Two years after this, another tour which he made on the Continent, seems to have been confined to France, the Netherlands, and Holland, which for the most part he had traversed before.

The only important production of Mr Leslie's latter years, and his crowning benefaction to this work, was his *Discourse on the Progress of Mathematical and Physical Science during the Eighteenth Century*; which constitutes the Fifth Dissertation in the first volume of this present edition. His arrangement of his materials, and his view of the whole subject, is comprehensive, vigorous, and spirited; while the greater ease and perspicuity of its style render this the most agreeable of all his writings.

The volumes of the *Edinburgh Philosophical Journal*, published between 1824 and 1829, contain some small contributions from him, entitled *Remarks on the Light of the Moon and of the Planets*; *Enumeration of the Instruments requisite for Meteorological Observations*; *Letter on the Coniometer*; and *Observations on the Theory of Compression, applied to discover the Internal Constitution of our Earth*. Even these small treatises display all the characteristic boldness and poetical dress of his speculations.

Early in the year 1832, on the recommendation of Lord Brougham, then Lord High Chancellor, he was created, along with several other eminent men of science, a Knight of the Guelphic Order. He was also a member of the Royal Society of Edinburgh, and in 1820 had been elected a corresponding member of the Royal Institute of France, the only distinction of the kind that he valued.

For a few years before this period, he had passed all his intervals of leisure at Coates, a small estate which he had

purchased near Largo, and which he loved to decorate and improve. In the last days of October, whilst engaged in superintending some improvements on his grounds, he exposed himself to wet, and caught a severe cold. This was followed by erysipelas in one of his legs, which, owing to his contempt for medicine, and an excessive confidence in his strength and durability, he neglected, and again imprudently exposed himself in the fields. He soon afterwards became dangerously ill, and expired at Coates, on the evening of Saturday, Nov. 3, 1832, in the sixty-seventh year of his age.

Surpassed by a few of his contemporaries in the same walks of science, in profundity of understanding, in philosophical caution, and in logical accuracy, he rivalled them all in that creative faculty, which discovers often by an intuitive glimpse the hidden secrets of nature, and in that subtlety and reach of discernment which seizes the finest and least obvious qualities and relations of things, and ministers to new and unexpected combinations of her powers. Possessing the powers of judgment and reason in less efficiency, he was often led, in his speculations, to results glaringly inconsistent. His credulity, often shown in affairs of ordinary life, induced him too often to indulge in unwarrantable applications of mathematical reasoning, to subjects altogether foreign to that science. For example, he finds an analogy between circulating decimals and the lengthened cycles of the seasons! False, however, though many of his theoretical notions may be, his exquisite instruments, and his experimental combinations, will ever attest the utility, no less than the originality of his labours, and continue to act as aids to farther discovery. His information, ample and accurate, not only in science, but in the general range of subjects, and especially in Scottish history, becomes more remarkable from its co-existence with his great power of invention,—a union by no means common. His conversation, unlike his writings in point of expression, was simple, unaffected, and correct. It had no wit, little repartee, and no fine turns of any kind; but it had a strongly original and racy cast, and was replete with striking remarks and curious information. His moral character was slightly blemished by a tendency to avarice, unbecoming in a philosopher, and by an occasional reluctance to acknowledge kindred merit; but these defects were more than counterbalanced by his child-like simplicity, social disposition, warmth of affection, and unchanging serenity of temper. He was never married. In person he was somewhat under the middle size, and corpulent, but strong and well limbed; and though his face was large and florid, there were about his eyes and forehead the distinct traits of no ordinary man. There is a bust of him by Joseph; a portrait, of the ordinary size, taken a few years before his death, by Wilkie; and a head, drawn at an earlier period, by Henning, which presents a striking likeness.

See SIXTH PRELIM. DISSERTATION, chap. vi., § 5.

Besides the works already mentioned, Leslie wrote *Observations on Electrical Theories*, published, in 1824, in the *Edinburgh Philosophical Journal*; and the articles in the seventh edition of this Encyclopædia, on *Achromatic Glasses*; *Acoustics*; *Aeronautics*; *Andes*; *Angle*, and *Trisection of Angle*; *Arithmetic*; *Atmometer*; *Barometer*; *Barometrical Measurements*; *Climate*; *Cold and Congelation*; *Dew*; *Interpolation*; and *Meteorology*.

LESLIE, a manufacturing town and borough of barony of Scotland, county of Fife, on an eminence on the left bank of the Leven, 10 miles S.W. of Cupar. It is neatly built, consisting chiefly of one street, and contains a parish and free church, and several dissenting chapels. The inhabitants are chiefly employed in flax spinning, bleaching, cotton spinning, &c. Pop. (1851) 1342.

LESSING, GOTTHOLD EPHRAIM, was born 22d January 1729, at Camenz, in Saxony, where his father, a pious and staunch Lutheran, was minister. He was the eldest son

Leslie
||
Lessing.

Lessing,
Gotthold
Ephraim.

of a numerous family, and received his early education at home. At the grammar school of Meissen, where he received the surname of "admirable," he distinguished himself, not merely by extensive reading, but by clear and independent thought. A paper sent to his father, at the new year of 1743, when he was only a boy of fourteen, and which was entitled, *On the Similarity of one Year to another*, discusses such high themes as the possibility of a golden age, and the doctrine of human deterioration. From Meissen he was sent to the University of Leipsic, where his parents designed that he should study theology. The lectures of Ernesti and Gellert, however, were spent on him in vain. Along with Christoph Mylius, his early bosom friend, and several other gay companions, he conceived a violent passion for the drama, and gave himself up to fencing, dancing, the theatre, and debt. Some torn pages of a comedy, however, found their way to Camenz in his box at Christmas, and the young dramatist was ordered home. To soothe his mother's anxieties, he laid his comic studies aside, and kindly wrote her a sermon. At Easter, he returned to college, with the view of studying medicine; but his old passion broke out anew, and carried everything before it. Finding his debts now grudgingly paid, and the supplies in hourly danger of being cut off, he followed his friend Mylius to Berlin, where they began a dramatic quarterly (*Beiträge zur Historie des Theaters*), which, however, only reached its fourth number. So little conscious was he of the peculiar service which he was destined to render to the literature of his country, that we find him about this time busily engaged in translating Klopstock's *Messiah* into Latin.

At the request of his parents, he resided for some time at Wittenberg with his brother, who was studying for the church; but he soon returned, unchanged in the bent of his genius, to Berlin, where, with Moses Mendelssohn and Nicolai, he plunged into a life of incessant literary activity. With the former he wrote his essay on Pope as a metaphysician (*Pope als Metaphysiker*), and with both he started the *Bibliothek der Schönen Wissenschaften*. In 1755 he removed from Berlin to Leipsic, whence he intended to travel into England; but he got no farther than Holland, and he retraced his steps to Leipsic soon after. In 1759 appeared those *Letters on Literature*, written in conjunction with Mendelssohn and Nicolai, which may be said truly to form an epoch in German literature. In 1760 Lessing went to Breslau, as government secretary to General Von Tauenzien, probably with the view of recruiting his health by change of scene, but more directly to fill his purse, which, even in its emptiness, had been generously open to his brother's wants. A new passion for gambling, however, robbed him of all, except his taste for study. After the drudgeries of his office were over, the busy writer of *Laokoon* might be seen bending over the *faro-table*, the perspiration starting from his brow, as he rushed into the thankless game with a strange impetuosity of mingled despair and superstition. In 1769 he went to Hamburg, as director of the theatre; but his love for the stage was now too cold to be rekindled, and most of his time was spent in antiquarian research. Here he wrote his letters to Klotz, and here he formed his intimacy with the pastor Götze, with whom he afterwards fought his most memorable polemic. All his exertions in this capacity scarcely kept poverty at bay, and he had serious thoughts of quitting Germany, to beg or starve more pleasurably at Rome, when his friend Ebert procured him the office of librarian of the Wolfenbüttel Library. This lifted him to a sudden affluence of L.90 per annum, with a free house, and firewood. Of the rare treasures of the library he has himself given an account; and he was scarcely installed in office, when he stumbled on a manuscript, by Berengar of Tours, in which he defends his opinions against Lanfranc; and its publication set at rest the doubts and

denials of his existence, long eagerly circulated in the Church of Rome.

In 1774 began the publication of the *Wolfenbüttelsche Fragmente*, a series of papers by an unknown hand, in which the writer attacks the historical basis of Christianity with a phalanx of arguments, which have since been spread out into a thin line by Strauss. These papers were long attributed to the pen of the librarian himself; but Samuel Reimarus, on his deathbed, set the question at rest by claiming them for his own. After a short and unsatisfactory visit to Italy and Vienna, Lessing returned to Wolfenbüttel; and, in 1776, he married Madame König, a lady whom he had betrothed at Hamburg, in hope of better days to come. His happiness, however, was not of long duration. She died in childbirth, in the spring of 1778, and left him to drown his grief in incessant literary toil. His old friend Götze, who had stepped into the arena with a pamphlet against the *Fragmente*, was the first to feel the edge of his sharp, clear, nervous prose; and so fierce was the assault, that the ministry of Brunswick, in alarm, prohibited the prolongation of the contest. Lessing, however, continued for some time to evade the prohibition by printing at Berlin, but hit at length upon a more deadly expedient. When a youth at college, he had been bold enough to introduce upon the stage scenes and personages foreign to the drama of his country. *Der Freigeist*; *Der Mysogyn* (the woman-hater); and *Die Juden*, are among the titles of plays written by him when a student at Leipsic. These were followed, in later life, by *Miss Sarah Sampson*; *Emilia Galloti*; *Philotas*; *Minna von Barnhelm*; and several others. Unwilling now to leave the sacred retreat of Wolfenbüttel, a martyr to a single mode of controversy, he dressed his opinions for the stage, and, in the mask of *Nathan the Wise*, spoke his estimate of Christianity with Brahminic calmness to the world. In this dramatized theology, he has probably given to his country a more powerful impress than any of its mighty thinkers from Luther to Schleiermacher. The *Education of the Human Race* (*Erziehung des Menschengeschlechts*), and one or two minor works, all posthumous, were the only contributions which he made, after its publication, to the progress of opinion.

With slow and leaden steps, exhausted and cheerless, Lessing sank into the grave. His few hours of activity were alternated with long and dreary fits of somnolency, from which he struggled in vain to free himself, till death somewhat prematurely closed his career, 15th February 1781. His works have been several times collected. The best edition is that by Wendelin von Maltzahn, Leipsic, 1852, and not yet (1857) completely published. The principal sources of information in regard to his life, are to be found in a short sketch by his nephew, and in the voluminous but somewhat undigested biography of Danzel.

Lessing stands as one of the great landmarks in the literary history of Germany. He followed Klopstock in evoking a national literature, which retained its elastic freedom till Goethe once more subjected it to foreign chains. While Klopstock, however, only pointed the way, Lessing led the advancing host; and the sublime tranquillity of the one was soon lost in the restless activity of the other. Lessing cannot be called a poet, and he is perhaps scarcely more entitled to be called a philosopher. He is more like a border chief treading restlessly the confines of both with fearless familiarity and a sublime but solitary lawlessness. Freely to rove in every path of human inquiry was to him a more royal prerogative than to wield the sceptre of a fixed dominion. In his athletic scepticism we see his superstitious horror of rest on its tragic side; but even in his most playful dramas and critiques there is a suppressed dialogue in every sentence, an undertone of conflict, generally faint as a dream, but swelling often into a wild and painful distinctness. In this respect he betrays a hidden nature immeasurably nobler than Voltaire,

Lessing,
Gotthold
Ephraim.

L'Estrange whose careless wit Lessing despised while wielding at will a keener wit of his own. No exposition of his opinions can more adequately represent the spring of his life than a saying which he repeated more than once, "that if God should hold truth in his right hand, and in his left, doubt, or the chase after truth, with the danger of wandering to and fro for ever in its search, and should bid him choose between the two, he would grasp the left hand and beg for doubt, with the words, 'Father, give me this—pure truth is for thee alone;'" and no comment can be more striking than the fact revealed by Jacobi, that when body and mind were both failing, the author of the *Education of the Human Race* was secretly resting his faith on the pantheism of Spinoza.

L'ESTRANGE, SIR ROGER, a political writer of the seventeenth century, was the youngest son of Sir Hamond L'Estrange, of Hunstanton Hall, Norfolk, and was born at the family seat in 1616. After receiving a liberal education, he commenced his public career by attending Charles I. on his expedition against the Scots in 1639. During the civil war he was a zealous royalist, and in 1644, having received a commission from the king, appointing him governor of Lynn, he endeavoured to wrest that town by surprise from the parliamentary forces, but was betrayed by two of his accomplices and lodged in prison. He was tried before the city court-martial, was condemned to death as a traitor, and sent to Newgate. As he had friends, however, in both houses of parliament, he was reprieved; and after lying in prison for nearly four years, was allowed to escape beyond the sea. Availing himself of the Act of Indemnity that had been passed in 1652, he returned to England in 1653; and after loitering about Whitehall for some time, and making personal application to Cromwell, he was allowed to live unmolested. This tampering with the ruling party was afterwards a galling weapon in the hands of his enemies, and was perhaps one of the reasons why the only reward he received from Charles II., after his restoration, was the invidious office of licenser of the press. Nevertheless, in several pamphlets which he published about this time, and in the *Public Intelligencer*, a newspaper which he started in 1663, he was a slavish supporter of the crown. His other paper, the *Observer*, begun some time after the Popish plot, was the organ of the Tory party, then on the ascendant, and was designed to exculpate the king from the charge of leaning towards Popery. On the accession of James II., he was knighted for "his unshaken loyalty to the crown," and sat in the parliament of 1685. When the king propounded his doctrine of toleration, L'Estrange, hesitating for the first time to agree with royalty, discontinued his *Observer*. At the Revolution, he was deprived of the office of licenser of the press; and shortly afterwards becoming imbecile, he died on the 11th of December 1704.

His political pamphlets, intended as they were, to suit the taste of the common people, swarm with vulgarisms and coarse and abusive epithets. He wrote also translations of the following works:—*Josephus' Works*, *Cicero's Offices*, *Seneca's Morals*, *Erasmus's Colloquies*, *Æsop's Fables*, *Quevedo's Visions*, *Bona's Guide to Eternity*, *Five Love-Letters from a Nun to a Cavalier*.

LETTERKENNY, a market-town and river port of Ireland, county of Donegal, on the Swilly, 18 miles S.W. of Londonderry. It consists of a single street and a square, and contains an Established church, a Roman Catholic, and several Presbyterian chapels; a national and other schools, a fever hospital, dispensary, and bridewell. Considerable trade is carried on, chiefly in agricultural produce, at the weekly market on Friday, and in exportation by the Swilly. Pop. (1851) 2180.

LEUCA, CAPO DI (*Salentinum Promontorium*), a cape on the coast of Naples, province of Terra di Otranto, forming

the extreme S.E. point of the Italian peninsula. N. Lat. Leucadia 39. 48., E. Long. 18. 22.

LEUCADIA, originally part of the mainland of the Greek continent, forms now one of the Ionian islands, being separated from the coast of Acarnania by a narrow artificial channel. The original inhabitants of the peninsula were Teleboæ and Leleges, but it was afterwards peopled by Acarnanians. In the seventh century before Christ, a new town called Leucas, a name derived from its white cliffs, was founded by the Corinthians under Cypselus, in the N.E. of this island near the isthmus. These colonists cut the channel through the isthmus, converting the peninsula into an island. This canal was afterwards choked up with sand, so as to prevent the passage of ships, which had accordingly sometimes, during the Peloponnesian war, to be conveyed across the isthmus. We learn from Polybius, that it was in this state in B.C. 218, but it was subsequently restored, and a stone bridge thrown across it,—one probably of the many works of Augustus, for facilitating communication throughout his extensive empire.

The Leucadians had three ships at the battle of Salamis, and, like most of the Dorian states, sided with the Lacedæmonians in the Peloponnesian war. In the contest between Philip of Macedon and the Romans, it took part with the former, but was reduced by the Romans after a gallant defence. It long continued to be a place of considerable importance, and was very early made the seat of a Christian bishopric. In A.D. 1467 it was seized by the Turks, by whom it was ceded to the Venetians in 1718. In 1810, the fort, called Santa Maura, was taken from a French garrison which had occupied it, after a siege of several weeks, by a detachment of English troops. The fort, which was originally built by the Turks, was ruined by an earthquake in 1825, and has not since been repaired. The island still continues in the possession of the English.

Leucadia is about 20 miles in length, by from 5 to 8 in breadth, for the most part of a rugged and uncultivated aspect, but rather more fertile and populous in the southern districts. It consists of a range of limestone mountains, the highest ridge rising about 3000 feet above the level of the sea, terminating in a bold headland on the N.E., whence the coast runs in a S.W. direction to the celebrated promontory of Sappho's Leap, the ancient Leucates. The island is visited by a rather serious earthquake about once in twenty years. Slight shocks occur almost every month.

The present chief town of Leucadia is Amaxichi, situate a mile and a half to the N.W. of the ancient city of Leucas. It is an ill-looking town, built in the most unhealthy part of the island, on the edge of a large lagoon; the houses, on account of the frequency of earthquakes, being seldom more than two storeys high. Its population is about 4000.

LEUCIPPUS, the founder of the Atomic Theory in Greek philosophy. The period in which he lived is unknown, but is generally supposed to have been in the fifth century before the Christian era. Elis, Abdera, and Miletus, have been severally assigned by different authors as his birthplace. According to Diogenes Laertius, he was the teacher of Democritus. By others he has been called the disciple of Pythagoras, of Melissus, and of Zeno the Eleatic. Aristotle, however, is not alone in asserting that the first principles of the atomic theory, though evolved by Leucippus, were particularly expounded by Democritus. In explaining the creation of the universe, they supposed that the two great principles in nature were a *vacuum* and a *plenum*. The *plenum* consisted of *atoms* infinite in number, and, as their name implies, indivisible. As a necessary consequence of their being many and not one, the atoms floated in the midst of the *vacuum*. Possessing, also, as their essential qualities, motion, solidity, and form,—in virtue of the first they began a rotatory movement; in virtue of the second they were prevented

Leuctra
||
Lëuwen-
hoeck

from merging into one simple body; and in virtue of the third, those of similar figure attracted each other. The atoms that were spherical, and consequently more moveable, meeting together formed fire; those that were not spherical formed, in their aggregations, the other three elements, air, earth, and water. The subtlest and most refined of the fire-atoms constituted the soul. Life, too, having been identified with respiration, was explained as being merely the flux and reflux of these spherical atoms. Here Leucippus seems to have stopped; but Democritus, following out these principles to their natural results, arrived at his system of Psychology, and at his theory of the First Cause, which he rather obscurely calls *Destiny*. The opinions afterwards became identified with the doctrines of Epicurus. See *EPICUREAN PHILOSOPHY*.

LEUCTRA, a village of Bœotia, situate between Thespiæ and Plateæ, in the territory of the former, celebrated as the scene of the great battle between the Spartans, commanded by Cleombrotus, and the Thebans, under Epaminondas, in which the former were defeated, and the supremacy of Sparta finally overthrown. See *SPARTA*.

LEUK, a village of Switzerland, canton of Valais, on the right bank of the Rhône, 15 miles E.N.E. of Sion. Seven miles N. of this village, at the head of the Lala torrent, and 4500 feet above sea level, are the Baths of Leuk, much resorted to by invalids. They are supplied with water from some hot springs which issue from the earth here at a temperature of about 124° Fahrenheit. The waters are slightly saline, and owe their value more to the mode of using them than to any intrinsic property of their own. Pop. of village, 620.

LEUSDEN, JOHN, a celebrated biblical writer, was born at Utrecht in 1624. After he had studied languages and mathematics at Utrecht, he repaired to Amsterdam to perfect his knowledge in Hebrew, by conversation with the rabbin. Here his attainments in oriental languages soon became so conspicuous, that in 1649 he was appointed Professor of Hebrew in his native city. After gaining the reputation of being one of the best Hebrew scholars of his day, he died in 1699.

His most important works are,—*Philologus Hebræus, editio tertia*, Utrecht, 1686; *Philologus Hebræo-Mixtus, editio quarta*, 1739; *Philologus Hebræo-Græcus, editio secunda*, 1685; *Onomasticum Sacrum*, Leyden, 1665 and 1684; *Clavis Hebraica et Philologica Veteris Testamenti*, Utrecht, 1682; *Novi Testamenti Clavis Græca cum Annotationibus Philologicis*, Utrecht, 1672; *Compendium Biblicum Veteris Testamenti*, 1694; *Compendium Græcum Novi Testamenti*, London, 1680; *Jonas Illustratus*, Utrecht, 1652 and 1692; *Joel Explicatus per Paraphrasim Chaldaicam*, Utrecht, 1657.

LEUTSCHAU, a town of N. Hungary, capital of the county of Zips, an affluent of the Hernad, 120 miles N.N.E. of Pesth. The town is ill laid out, with narrow and irregular streets. The chief public buildings are the town-house, containing a gallery of paintings, the church of St Jacob, with an organ said to be the largest in Hungary. There are a Roman Catholic and a Protestant gymnasium, the latter the oldest in Hungary. Mead and linen are made here; and a trade in fruit, saffron, and hops is carried on to some extent. Pop. 5500.

LËUWENHOECK, ANTHONY VAN, a famous naturalist, was born at Delft, in Holland, in 1632. At first he was well known as a grinder of optical glasses; and though destitute of a liberal education, was induced to use the excellent microscopes which his skill had made, in examining the textures and fluids of animal life. His success in anatomy and physiology was soon so marked, that an account of some of his discoveries was published through the influence of Dr Grew in the *Philosophical Transactions of the Royal Society of London*, of which he became a Fellow

Leuze
||
Leven.

in 1680. His numerous contributions to the records of that society are comprised between Nos. 94 and 380. In 1697 he was elected a corresponding member of the Academy of Sciences at Paris; and in the following year, his fame had become so far-spread, that Peter the Great, when passing through Delft, sent for him and requested to see his "admirable microscopes," and the wonderful secrets which they revealed. The naturalist showed him the circulation of the blood in the tail of an eel. Lëuwenhoeck died at his native place on the 26th of August 1723.

One of his most important investigations was that by which he discovered, in 1690, that the arteries and veins were continuous, an opinion, however, which he had contradicted in a memoir communicated to the Royal Society of London in 1686. The theory of the fermentation of the blood then universally held, he refuted by proving experimentally, that there were no bubbles of air in the blood, and therefore there could be no fermentation. He experimented, but with little success, on the form of the globules of the blood, and likewise on the brain and nerves, which he showed in 1717 to be of fibrous texture, with blood-vessels interspersed between the fibres; a view which has since been discovered to be very nearly correct. Another object of his study was the crystalline lens, the different coats of which he described with accuracy, illustrating his descriptions with figures. He also examined the spermatic animalcules, and asserted that he had discovered them; a claim which was contested with Ludwig, Hamm, and Hartsaeker. Others of his investigations ended in mistakes, owing partly to his deficient erudition, and partly to a certain native stubbornness, which led him to consider a confession of error to be degrading.

Lëuwenhoeck contributed 26 papers to the *Memoirs of the Academy of Sciences*. A collection of his works, printed (for the most part separately) in Dutch at Delft and at Leyden, were translated into Latin under the title of *Arcana Naturæ delecta*, Delft, 1695–1699. The best collection of his works, translated into Latin, consists of his Correspondence, 2 vols. 4to, Leyden and Delft, 1719; and *Arcana*, 2 vols. 4to, printed at Leyden in 1722.

LEUZE, a manufacturing town of Belgium, province of Hainault, on the Tournay and Ath Railroad, 12 miles E. of the former. The town is well built, and its streets are clean. It manufactures cotton stuffs, linen, and hosiery; and has breweries, bleaching and dye works. Pop. (1850), 5842.

LEVANT (Italian *Levante*, the East), a term originally used by the Venetians and Genoese to designate the coasts of the Mediterranean E. of Italy; but now commonly applied to the coasts of Asia Minor, Syria, and Egypt, on the Mediterranean. See *MEDITERRANEAN*.

LEVANTE, a Sardinian province. See *GENOA*.

LEVANTO, a seaport and fortified town of the kingdom of Sardinia, on the E. shore of the Gulf of Genoa, 12 miles N.W. of Spezia. The town, though dirty, contains several fine edifices, the chief of which is the church consecrated in 1463, and built after the style of the Genoa cathedral. Wine and oil are exported hence in considerable quantities. The former is made at Vernazza, an adjoining village. Pop. 4600.

LEVEE (French, *lever*, to rise), is the name given to the ceremonial of receiving visitors on state occasions. The name is derived from the fact of the visit taking place in the morning, *i.e.*, shortly after rising. A levee may be for gentlemen only, or for ladies only; whereas at a "drawing-room" both may be present.

LEVEL, and LEVELLING. See *SURVEYING*.

LEVEN, a burgh of barony and sea-coast town of Scotland, Scoonie parish, Fifeshire, on the Firth of Forth, and at the mouth of the Leven Water, 18 miles N.N.E. of Edinburgh. Flax spinning and the manufacture of linen

Leven
||
Levites.

and sailcloth form the chief occupations of its inhabitants. There are also iron-foundries, bleaching-works, brick and tile works, an ochre manufactory, and a rope-walk, with collieries and stone quarries in the vicinity. The harbour is supplied with a quay, and admits vessels of 300 tons at high spring tide. By railway the town has communication with Edinburgh, Perth, and Dundee. Pop. (1851) 2083.

LEVEN, *Loch*, an arm of the sea on the W. coast of Scotland, branching off from Loch Linnhe eastwards, and separating the counties of Argyll and Inverness. It is 12 miles in length, and from half a mile to 1 mile in breadth.

LEVEN, *Loch*, a lake of Scotland, Kinross-shire. See KINROSS-SHIRE.

LEVITES, the descendants of Levi, through his sons Gershon, Kohath, and Merari, whose descendants formed so many sub-tribes or great families of the general body. In a narrower sense the term Levites designates the great body of the tribe employed in the subordinate offices of the hierarchy, to distinguish them from that one family of their body—the family of Aaron—in which the priestly functions were vested.

In the wilderness the office of the Levites was to carry the tabernacle and its utensils and furniture from place to place, after they had been packed up by the priests. In this service each of the three Levitical families had its separate department; the Gershonites carried the hangings and cords of the tabernacle, for which they were allowed two wains, each drawn by four oxen. The Kohathites carried the ark, the table of shew-bread, the candlestick, the two altars, and such of the hangings as belonged to the sanctuary; for this they had no wains or oxen, the whole being carried upon their shoulders. The Merarites had charge of the substantial parts of the tabernacle—the boards, pillars, bars, bases, &c., and also all the ordinary vessels of service—for which they were allowed four wains and eight oxen. In this manner they proceeded in their journeys; and when they settled in a place, and had erected the tabernacle, the different families pitched their tents around it in the following manner: the Gershonites behind it on the W., the Kohathites on the S., the Merarites on the N., and the priests on the E. They all assisted Aaron and his sons in taking care of, and attending on the Tabernacle, when it was pitched; but they were allowed to take no part in the services of the altar.

This was the nature of their service in the desert: but when they entered the land of Canaan, and the tabernacle ceased to be migratory, the range of their service was considerably altered. While part attended at the tabernacle, the rest were distributed through the country in the several cities which were allotted to them.

In the time of David, when the number of the priests and Levites had much increased, a third and very important alteration was effected. Like the priests, the Levites were also divided into twenty-four courses. In the Book of Chronicles we have four times twenty-four courses of Levites mentioned, but all their employments are not distinctly stated. The most conspicuous classification is that of twenty-four courses of porters and servitors, and twenty-four of musicians.

The office of the porters was to open and shut the doors and gates of the temple courts, at which they also attended throughout the day to prevent the entrance of any harmful or unclean person or thing. They had also the charge of the treasure-chambers in their respective wards; for we find four of the chief porters holding this trust in 1 Chron. ix. 26.

Besides acting as porters and servants during the day, we learn that they were also the guards of the temple. Minute particulars with reference to the second temple are given by the rabbinical and other authors; and, so far as they are correct, which they seem to be in substance, they may be supposed to apply equally well to the first temple,

Levites.

from which they must have been in the main transmitted. The whole number of guards to the temple at night is stated to have been twenty-four, of whom three were priests. These are described as having been under an overseer, called “the man of the mountain of the house.”

Thus one division of the Levites was employed as porters during the day, and another as guards during the night: a third division served as musicians. A catalogue of these is given in 1 Chron. xxv. 1-9, according to their employments; and another, according to their courses, in 1 Chron. xxv. 9-31. On grand occasions, when a full band was formed, the family of Heman sung in the middle (1 Chron. vi. 33-38), the family of Asaph on the right hand (vi. 39-43), and the family of Ethan on the left. The ordinary place for the musicians was at the east end of the court of the priests, between the court of Israel and the altar.

It seems that the singers could never be under twelve, because that number was particularly mentioned at their first appointment (1 Chron. xxv. 9); but there was no objection to any larger number. The young sons of the Levites were, on such occasions only, allowed to enter the court of the priests with their fathers, that their small voices might relieve the deep bass of the men (*Gemara. tit. Succah*, ch. v.); and for this authority was supposed to be found in Ezra iii. 9.

At thirty years of age they became qualified for every part of the Levitical service. This was under the tabernacle; but when the temple was built, and bodily strength was less required, the age was reduced to twenty. After fifty they were no longer called upon to serve as a matter of obligation; but they might attend if they thought proper, and perform any usual service which was not considered burdensome. Thus, in the wilderness, they ceased at that age to carry any part of the burdens when the ark and tabernacle were removed. In addition to the more menial duties before described, the Levites doubtless assisted the priests in the important work of the education of the people.

The subsistence of the Levites was provided for in a peculiar manner. It consisted, first, of a compensation for the abandonment of their right to one-twelfth of the land of Canaan; and, secondly, of a remuneration for their services in their official capacity as devoted to the services of the sanctuary. The territorial compensation lay in the 48 cities which were granted to the whole tribe, including the priests. These cities were scattered among the different tribes, as centres of instruction, and had 1000 square cubits, equal to above 305 English acres, attached to each of them, to serve for gardens, vineyards, and pasturage. It is obvious, however, that this alone could not have been an adequate compensation for the loss of one-twelfth of the soil, seeing that the produce of 305 acres could not in any case have sufficed for the wants of the inhabitants of these cities. The further provision, therefore, which was made for them must be regarded as partly in compensation for their sacrifice of territory, and as a remuneration for the dedication of their services to the public. This provision consisted of the tithe, or tenth of the produce of the grounds allotted to the other tribes. The simplest view of this payment is to regard it, first, as the produce of about as much land as the Levites would have been entitled to if placed on the same footing as the other tribes; and also as the produce of so much more land, which the other tribes enjoyed in consequence of its not having been assigned to the tribe of Levi.

When first numbered after the Exodus, the Levites amounted to 22,300, of whom 8580 were fit for service. Just before entering Canaan, they had slightly increased, viz., to 23,000. In David's time there were 38,000 fit for service (1 Chron. xxiii. 3-5), which, at the same ratio as above, would give a total of about 96,000. After the revolt of the ten tribes, they joined themselves to Judah and Benjamin. The restoration of the house of David in Joash

Leviticus was mainly effected by the Levites (2 Chron. xxiii. 1-11). After the edict of Cyrus, only about 350 of them returned to Jerusalem. During the captivity they seem to have lost, in a great measure, a proper sense of their obligations and duties, for many of them married idolatrous wives (Neh. x. 9-13). In the apocryphal books the Levites are not spoken of, and only a few notices of them occur in the New Testament, where they are also called scribes and lawyers.

LEVITICUS. See **PENTATEUCH.**

LEWES, a parliamentary borough and market-town of England, county of Sussex, on the Ouse, here crossed by a stone bridge, 8 miles N.E. of Brighton, and 50 miles S. of London by railway. It stands on a declivity sloping down to the water side, and is surrounded by hills. The inhabitants are principally employed in rope-making, brewing, tanning, and lime-burning, as well as in the grain, malt, and cattle trade. By the River Ouse, which becomes navigable 2 miles above the town, goods are sent down to Newhaven for shipment to London and other places.

Lewes is one of the oldest towns in England, and numerous remains of Roman art have been excavated in the town and neighbourhood. It was strongly fortified by the Saxons; and after the Norman conquest, when it fell to the lot of William de Warren, son-in-law of William I., a castle, the ruins of which occupy a commanding position above the town, was erected to keep the inhabitants in awe. Earl de Warren also founded a monastery here, now a ruin. In May 1264, the famous battle between Henry III. and the barons under Simon de Montfort was fought in the vicinity, when the latter were victorious. Lewes has returned two members of parliament from the time of Edward I. Pop. (1851) 9533.

LEWIS, the northern portion of the largest and most northern of the islands of the outer Hebrides, lying off the W. coast of Scotland, from which it is separated by the Minch, a sea about 30 miles across. The name Lewis (Celtic, *Leodhus*) is probably derived from Leod or Leodus, son of Thorfin, the last Orcadian viceroy that swayed the Norwegian viceregency of this island. Leodus allocated Lewis to his eldest son Torquil, and Harris to his younger son Norman. These were the first M'Leods, and the ancestors of the Siol Torquil and Siol Tormaid, who so long held these respective properties. Harris, the southern portion of this island, is much the smaller of the two, and is appended to Inverness-shire, whereas Lewis forms part of Ross-shire. The boundary line between the two divisions extends from Loch Resort on the W. to Loch Seaforth on the E., where the island is only about 6 miles in breadth. Lewis is triangular in form, having its base towards Harris, while its apex extends northward, and terminates in the Butt. It is 45 miles in length, by 15 in average, and 30 in extreme breadth; between N. Lat. 58. and 58. 33., and W. Long. 6. 10. and 7. 10. Area, 417,460 acres. The coast is deeply indented by branching arms of the sea, many of which are very capacious, and afford secure anchorage. On various parts of the coast and in these estuaries are numerous small islands which yield excellent pasturage. The chief promontories of Lewis are the Butt, Tiompan, Chicken, Kebuck, and Gallan Heads—all bold and precipitous cliffs rising abruptly from the sea to a great height.

Lewis and Harris are distinct not only in name but also in their general features. The latter consists mainly of an irregular group of comparatively lofty mountains, some of them rising to the height of 3000 feet, rugged and precipitous on their eastern sides, but generally verdant on their

western declivities. That portion of Lewis bordering upon Harris partakes of the same mountainous character, attaining a height of 1400 feet in the Peak of Swaineval, and 900 in the Hill of Roineval. Alluvial straths of fine pasturage, and vales of romantic beauty interrupt and variegates this hilly district, which may be regarded as terminating at a line extending from the head of Loch Roag on the W., to that of Loch Shell on the E. Northward from this line Lewis presents a somewhat monotonous undulating expanse of table-land, interrupted only by a few elevations, the loftiest of which, Monach, does not exceed 810 feet. Throughout the interior, hill and dale are alike clothed by vast accumulations of peat-moss, varying from 2 to 18 feet in depth—studded with numerous lakes, and intersected by silent streams and quiet rivulets. This dark-grounded interior is bordered all along the sea coast by a fringe of arable land, varying in breadth from half a mile to 3 miles, and dotted over with populous villages. The arable soil consists generally of decomposed moss, varying in quality and fertility according as it is intermixed with and based upon siliceous or shelly sand, alluvial till, gravelly loam, or marly clay. The fundamental substratum of Lewis consists of gneiss. On the W. shore it is traversed by veins of granite, and assumes various curves and contortions from granitic disturbance. Near the Butt there are rock masses of orange-red felspar containing laminar scales of argillaceous schist, and beds of green compact felspar. Partial deposits of limestone occur at several places on the N.E. coast. Quantities of bog iron ore protrude in many places, and its prevalence is indicated by the ferruginous impregnation of numerous chalybeate springs. In Harris, Dr Macculloch found those rather rare minerals, *Sahlite*, and dark green *Coccolite*, in serpentine imbedded in limestone.

The climate of Lewis is mild and equable, and its humidity is much under the average of that of Scotland. From its flatness and the absence of high hills, it often escapes the contents of condensed clouds; and the entire surface is exposed to the action of the dry N.E. winds which prevail in spring, and often till midsummer, when the moors are thoroughly exsiccated. The great mildness of the climate, however, is no doubt chiefly due to the influence of the gulf stream. The temperature, even in the interior, rarely continues long at the freezing point, and snowfalls are of very brief duration. Observations taken for nearly four years at Stornoway, in N. Lat. 58. 12., give the mean annual temperature of the—

Year.	Winter.	Spring.	Summer.	Autumn.	Average annual fall of Rain.
46° 5'	40° 8'	40° 5'	51° 1'	51° 6'	30.2 inches.

The extremes of temperature rarely extend over more than 30 degrees from 35° to 65°. The animal kingdom in Lewis is especially rich in the ornithological department. The swan, grey goose, rain-goose, eider-duck, teal, widgeon, heron, snipe, woodcock, red grouse, ptarmigan, are among the most important. Otters and seals abound on the rivers and shores; and deer and hares are common.

The most remarkable ancient remains are the so-called Druidical standing stones, or Temple of Callanish, perhaps the most perfect in Britain. They are 43 in number, arranged in a cruciform manner, with a circle at the intersection. The long leg of the cross extends N. and S. 600 feet, and the transverse line at right angles measures 200 feet. Both measurements include the circle, which is 63 feet in diameter, consisting of 12 stones, ranging from 7 to 9 feet in height, with a central obelisk 15 feet high. The N. extremity of the long leg of the crucifix is formed into an avenue by two parallel lines of 16 obelisks, generally from 5 to 6 feet in height, the loftiest being 13 feet. They all rest on a causewayed base, in which they are firmly impacted by small stones. On a lower eminence, half a mile from the Callanish Temple, there is another cluster of

Lewis.

Lewis.

standing stones disposed into two concentric circles. They are nearly uniform in height, but are deeply imbedded in growing moss. In its vicinity there is another irregular semicircular group of erect stones; and throughout the country there are various specimens, single and in pairs, of those standing obelisks, probably erected as tombstones or cenotaphs, commemorative of the downfall or achievements of noted warriors. Rounded conical tumuli and monumental cairns are abundant. Belonging to a later age are many remains of circular *duns* or round towers, the most perfect of which are those of Bragar and Carloway. The latter was originally upwards of 30 feet high, constructed of unhewn stones, with a double dry wall, containing spiral passages, from which the besieged could aim their arrows at assailants. It is very broad at the base, gradually narrowing and tapering towards the summit. We find also here, particularly on the W. coast and towards the Butt extremity, numerous small chapels and religious cells, generally insignificant in size, but strongly built of stone, cemented by a shelly mortar, which still retains its hardness and tenacity. The most perfect in design and architectural integrity is M'Leod's Chapel at Oreby, dedicated to Saint Molonach, and which was till recently much frequented by incurables for the healing virtues believed to be inherent in its consecrated precincts.

Since Lewis came into the hands of the present proprietor, Sir James Matheson, in 1844, large sums have been expended in carrying out improvements on the estate, as well as ameliorating the physical, social, and intellectual condition of the people. In the short space of seven years, the sums so spent equalled the purchase price of the property, L.190,000. The erection and endowment of educational institutions; the introduction of improved modes of cultivation, and improved breeds of horses, sheep, and cattle; and the institution of cattle and horticultural shows, are among the means that have been adopted. Besides improving and repairing 80 miles of roads formerly constructed, the present proprietor has formed about 100 miles of new roads, with several bridges. The great proportion of the arable land is in the hands of small crofters holding allotments varying in extent from 3 to 8 acres; and to show how much the inhabitants are dependent for food on external supplies, it may be mentioned, that in the seven months from 1st January to 31st July 1855, no less than 18,932 bolls of meal, costing about L.20,825, were imported, and that in consequence of only a partial failure of the potato crop of 1854. The total failure of the potato crop of 1846 entailed an outlay (borne, in the first instance, solely by the proprietor) of L.29,079 for meal alone. To obviate, in some measure, the evils arising from over-population, the proprietor has from time to time furnished free means of transit to other parts to such as were willing to accept of them; and, accordingly, in 1851-52 and 1855, about 1800 souls left the island for various parts of Upper and Lower Canada. An opportunity of free transit is now annually provided.

Great efforts are being made to introduce scientific modes of cultivation; and, with that view, about 2000 acres of previously untitled moorland and meadow pasture have been reclaimed, and a great portion of it converted into large model-farms, held by skilful lowland tacksmen, who exhibit the practical value of the most improved modes of cultivation. At the cattle shows, prizes are annually adjudged to the best specimens of every variety of farm stock and produce.

Lewis is divided into four parishes, each having its own church, school, and manse. Of late years the districts of Cross and Knock have been converted into *quoad sacra* parishes, having 2 churches. There are 8 Free churches, 5 of which have settled pastors, while the other 3 are supplied by probationers; and there are several Free Church schools in each parish,—the whole island numbering 38, showing an annual attendance of 2505 pupils. The few

Roman Catholics on the island receive periodical visits from an ecclesiastic of that persuasion. Here, as in most parts of the Highlands of Scotland, only a small fraction of the people remained with the Established church at the Disruption. More than 19-20ths of the inhabitants of Lewis belong to the Free Church.

The fisheries are the most important branches of industry carried on here. In 1855, 294 boats were engaged in the herring-fishery at the various stations; 35,227 barrels of herrings were cured, and 4000 taken and consumed uncured, the probable value of which was about L.56,840. In that year 903 tons of cod, ling, or hake were cured, and 250 tons taken and consumed uncured, the probable value being about L.17,043. The number of fishermen and boys employed in manning the boats was 2982; persons employed in gathering bait, baiting lines, as carters, &c., 2900. An improved slip for the launching of boats is now in the course of erection, under the direction of the proprietor and Scottish Fishery Commissioners, at the port of Ness, the great centre of the Lewis deep-sea fishing. The quantity and estimated approximate value of the exports from Lewis, in 1855, were as follows:—

Articles.	Quantity.	Value.
Smoked Haddocks.....barrels	800	L.1,600
Herrings.....	40,000	60,000
Cattle.....No.	1,700	6,800

Total,		L.98,093

Stornoway, the only town of Lewis, and the capital of the Western Hebrides, is situate at the head of a bay on the E. side of the island. It is well and regularly built, and its streets are lighted with gas. The most prominent of its buildings are the parish church, Free church, and Episcopal chapel; several of the schools, jail, and the masonic lodge. On an eminence, overlooking the town, is the magnificent mansion of the proprietor, recently erected in the castellated Tudor style. The castle grounds are extensive, and laid out with great taste. The industrial female seminary in Stornoway is a neat and commodious building, erected and endowed by the proprietor and his lady in 1847, at a cost of more than L.2000. It is attended by about 150 girls of the poorer classes, who are instructed in Ayrshire flowering needlework, domestic millinery, and laundry work, as well as the elementary branches of education. The masonic lodge contains elegant assembly rooms, reading rooms, and a public library. Stornoway has a branch office of the National Bank of Scotland, custom-house, a savings bank, Sailors' Home Hospital, and gas and water works. There are also commodious piers, and a building-dock, with a Morton's patent slip, worked by steam, and fitted to haul up ships of 800 tons burden. The entrance to the harbour is marked by a lighthouse and beacon. Near Stornoway there is an extensive tilery, for manufacturing bricks and tiles, erected at considerable expense by the proprietor. He has also introduced the tussac grass pertaining to the Falkland Islands, which appears to thrive remarkably well in the vicinity of the Castle of Stornoway. On 31st December 1855, the number and tonnage of vessels registered as belonging to the port were,—not above 50 tons burden, 38; tonnage, 989; above 50 tons, 12; tonnage, 1245. During that year the number and

tonnage of vessels that entered and left the port were,—coastwise, sailing vessels, inwards, 98; tonnage, 4564: outwards, 38; tonnage, 1418: steam-vessels, inwards, 85; tonnage, 16,961: outwards, 87; tonnage, 17,102;—colonial trade, sailing vessels, inwards, 2; tonnage, 63;—foreign trade, sailing vessels, inwards, 13; tonnage, 832: outwards, 42; tonnage, 2119. Pop. of Stornoway (1841), 1354; (1851), 2440. Pop. of Lewis (1755), 6386; (1831), 14,541; (1841), 17,037; (1851), 19,711.

LEWIS, MATTHEW GREGORY, author of *The Monk*, was the son of the Deputy Secretary-at-War, and of a daughter of Sir Thomas Sewell, Master of the Rolls, and was born at London in 1773. While attending Westminster school, he early evinced that taste for theatrical displays, and for books of romance and mystery, which his after years so inveterately confirmed. After studying for a short time at Christ Church, Oxford, he repaired to Germany, with the design of acquiring the language of that country; and there the perusal of the drama, and the wild fictions of the Germans, quickened his own invention, and he produced, in 1795, his most celebrated work, *The Monk*. Full of supernatural horrors, and scenes of blood and demoniacal cruelty, this novel presented a feature of fresh interest to the English public, and became speedily popular; but his coarse and minute handling of the lower passions verged on licentiousness, and nearly brought him under the punishment of the law. The fame thus acquired enabled him to obtain a seat in parliament for Hindon; but his talents were not those of a statesman, and he never ventured to address the House. His play of the *Castle Spectre*, produced on the stage in 1797, rivalled the reputation even of his *Monk*. An interview which he had with Sir Walter Scott at Edinburgh, in 1798, led to the contribution of several noble ballads by the latter to the *Tales of Wonder*, published by Lewis in 1801. On the death of his father, Lewis inherited a large sum of money, and plantations in the West Indies, which he visited in 1815. After securing the affection of his slaves by his kindness, and evoking many public demonstrations of their regard, he returned to England in 1816. But the mismanagement of his affairs recalled him to his estates in the following year; and on his homeward journey he died of fever in the Gulf of Florida, in July 1818.

His novels and numerous plays all exhibit the same extravagant taste for deeds of horror and mystery as his *Monk*; and their popularity, great on their first appearance, speedily declined on the advent of a purer public taste. His poetry, which consists chiefly of songs and ballads, inserted in his prose works, is deficient in passion and imagery; but along with elegance and lucidness of diction, possesses a finished and a musical flow of versification, which drew forth the warm commendation of Sir Walter Scott. The best, however, of all his productions is his *West India Journal*, written during his first voyage, and published in 1833, a work which evinces a talent in describing manners, that might have earned for its author a more during fame than that of his early days. His discretion, good feeling, and unselfish generosity, are shown to great advantage in his *Life and Correspondence*, published in London in 1839.

Next to the *Monk*, his most popular novel is the *Bravo of Venice*, 1804, which has since been reprinted. Of his numerous plays, *The Castle Spectre* alone is still acted. His ballads of *Alonzo the Brave* and *Durandarte* are the most popular of his poems.

LEXICON. See DICTIONARY.

LEXINGTON, a town of the United States of N. America, capital of Fayette county, Kentucky, is situate on Town Fork, a feeder of the Elkhorn, 65 miles E. of Louisville by rail. Its streets are well laid out, and the surrounding country, which is undulating and highly fertile, contains many elegant mansions. The chief public

VOL. XIII.

|
Leyden,
John.

edifices are,—Transylvania University, the State Lunatic Asylum, the public library, and churches. Besides these, there is a graceful monument erected to the memory of Henry Clay, who resided for some time at Ashland, a short distance from the town. The legal and medical departments of the Transylvania college have become important institutions. In 1854, the latter had 1351 graduates, forming the third largest number among the colleges of the United States. The manufactures of the town are important, including ropes, bagging, iron machinery, and carriages. In 1850 there were 15 factories engaged in hemp manufacture, employing 600 persons, and making yearly 2,500,000 yards of bagging, and 2,000,000 lb. of rope; while in the neighbourhood there were nearly as many establishments engaged in the same work. Hemp is grown largely in the state. By rail the town is connected with Louisville, Danville, Cincinnati, and other large towns. Lexington, the second oldest town of Kentucky, was founded in 1776, and for sixteen years continued to be the capital of the territory, when, in 1792, the government was transferred to Frankfort, the present state capital. Incorporated 1782. Pop. (1854) about 12,000.

LEYDEN (anc. *Lugdunum Batavorum*), a celebrated city of Holland, province of South Holland, on the Rhine, or rather on that branch of it that retains the name, 10 miles E.N.E. of the Hague, and 23 miles S.W. of Amsterdam, with both of which it is connected by railway. It is surrounded with a rampart, outside of which is a wet ditch crossed by eight bridges leading to as many gates. The River Rhine flows through the heart of the town; and, like other Dutch towns, Leyden is traversed by numerous canals which divide it into about fifty small islands communicating with each other by a great number of bridges. The streets are usually long, broad, and well paved; and the houses are generally of a superior class. The *Breede Straat* is nearly two miles in length, and is reckoned one of the finest streets in Europe. The town-hall is a picturesque old building, founded in 1574, and containing a valuable collection of paintings. St Peter's church, built in 1315, is the largest and finest in the city, and contains among its monuments one to the celebrated physician Boerhaave. The remains of a round tower, called the *Burg*, stand on a slight eminence in the centre of the town, and from the walk round the top the finest view of the city and neighbourhood is obtained. It is said by some to have been built by Drusus, though others ascribe it to Hengist about A.D. 450. Near the *Burg* stands the church of St Pancras, built in 1280, and containing the monument of the brave burgomaster Vanderwerff, who defended the city against the Spaniards in 1574. The University of Leyden, long one of the most distinguished seats of learning in Europe, was founded by the Prince of Orange in 1575, to reward the inhabitants for their bravery in defending the town against the Spaniards. Among its professors were Scaliger, Heinsius, Gomarus, Arminius, Boerhaave; and among its students Grotius, Descartes, Goldsmith, and Fielding. It has faculties of theology, law, medicine, science, and literature; and has usually from 600 to 700 students. It has also a valuable library, botanic garden, observatory, museums, &c. (See article HOLLAND.) There are likewise many fine private libraries and museums, among which may be mentioned the Japanese collection of Dr Siebold. The manufactures are unimportant, but it carries on some trade in grain, butter, and cheese. Historically, Leyden is chiefly noted for the gallant and successful defence made by the inhabitants in 1574 against the Spaniards under Valdez. The siege lasted for about five months, during which the inhabitants endured the greatest suffering from famine and pestilence. Pop. (1855) 37,029.

LEYDEN, JOHN, a celebrated linguist, antiquary, and poet, was born on the 8th of September 1775, at Denholm, a

Leyden,
John.

village on the banks of the Teviot, in the parish of Cavers, and county of Roxburgh. His father was a shepherd, and was descended from a long line of farmers who had lived on the estate of Cavers. From his second to his sixteenth year, Leyden lived with his parents in a retired cottage near the foot of the "stormy Ruberslaw," where he was taught to read by his father's mother, and where his favourite books were the Metrical Histories of Bruce and Wallace, the Poems of Sir David Lindsay, the *Arabian Nights' Entertainments*, and *Paradise Lost*. He learned writing, arithmetic, and the elements of Latin grammar, during a short attendance of three years at the school of Kirktown; and after studying Latin and Greek for two years under Mr Duncan, a Cameronian minister at Denholm, he entered the University of Edinburgh in November 1790. There, though his knowledge was at first very inaccurate, and the language in which he expressed his ideas so awkward as to set his fellow-students in a roar, he soon became noted for his attainments, not only in the prescribed studies, but in French, Spanish, Italian, German, and the ancient Icelandic. The vacations were generally passed in his native wilds amongst his own relations, with the exception of the summer of 1792, when he acted as assistant, with little success, in a school at Whitebanklee or Clovenfords, a village on the skirts of Ettrick Forest. At this time his appearance was very prepossessing. He was ruddy and fair, with a frame rather delicate than robust, and an expression of great good nature and gentleness in his features.

In November 1793 he began the study of divinity, but at the same time devoted much of his attention to historical research, to philology, to metaphysical speculations, and to natural history and medicine. He was a member of various debating societies, in all of which he distinguished himself by the fluency and copiousness of his unpremeditated harangues, rather than by any graceful or polished eloquence. In one of these institutions, he contracted an intimacy with Henry (now Lord) Brougham, and with Dr Thomas Brown and Francis Horner. About the same time he formed an acquaintance with Dr Robert Anderson, editor of the *British Poets*, and Thomas Campbell.

When he had completed his theological education, he accompanied the two sons of Campbell of Fairfield to St Andrews in 1797, where he attended the lectures of Dr Hunter, professor of humanity, and of Principal Hill, one of the divinity professors. He also entered the Theological Society, and was soon considered the best speaker, among such members as Professor Duncan of St Andrews, Lord Campbell, and Dr Chalmers. From the presbytery of St Andrews he received license to preach in May 1798; and returning to Edinburgh he preached frequently, but without attracting any popular admiration.

In the winter of 1798 he attended some of the medical classes, and at this period inflicted a lasting injury on his health, and nearly lost his life, by his rash and unskilful treatment of a complaint which he believed to be an attack of colic, but which proved to be *enteritis*. In addition to his duties as resident tutor in the family of Mr Campbell, he had been engaged as a writer in the *New London Review*; and, amongst other articles, contributed those on Horne Tooke's *Diversions of Purley*, on Dr Thomas Brown's *Observations on Zoonomia*, and on Vallancey's *Sanscrit History of Ireland*.

In the summer of 1799 he published *A Historical and Philosophical Sketch of the Discoveries and Settlements of the Europeans in Northern and Western Africa, at the close of the Eighteenth Century*. This interesting work, although written in about six weeks, whilst the author was in bad health, and at a distance from books, exhibits proofs of extensive information and sound reflection. An enlarged edition of it was published in 1817 by Mr H. Murray.

Through Mr Richard Heber, to whom he was intro-

duced by Mr Constable, he became acquainted with the most distinguished literary characters in Edinburgh, and, amongst others, with Sir Walter Scott, whom he greatly assisted at this time in editing the *Minstrelsy of the Scottish Border*, by recovering old ballads from oral tradition, and by communicating spirited imitations of the ancient bards, and valuable materials for the notes.

In 1800 a plan formed to establish him as assistant and successor to the minister of his native parish, failed, in consequence of the reluctance of the incumbent to agree to it. Soon afterwards, an attempt which he made to obtain the professorship of rhetoric and belles-lettres in Edinburgh, was also frustrated.

About this time he made two successive tours through the Highlands, and collected much curious information, which was never published. He wrote several poems, founded on the remains of Celtic story, one of which, the beautiful ballad of *The Mermaid*, has been inserted in the *Border Minstrelsy*. In 1801 he contributed to Lewis's *Tales of Wonder*, and published an edition of *The Complaint of Scotland*.

In 1802 he contributed many articles to the *Scots Magazine*, of which he had been newly appointed editor. He was also employed in collecting the papers of the Highland Society for publication; and he edited a volume entitled, *Scottish Descriptive Poems, with some Illustrations of Scottish Literary Antiquities*. Early in this year he offered to the African Society to explore the interior of that continent, in which so many Europeans have perished. His friends, alarmed at this, became eager to obtain for him an Indian appointment; and, through the interest of Mr William Dundas, he was nominated assistant-surgeon in the Company's service, on condition that he should take a surgical degree. After intense study for six months, he received the necessary diploma. The degree of Doctor of Physic was conferred upon him by the University of St Andrews, on the 7th August 1802. Meanwhile, he had finished his longest poem, *Scenes of Infancy*.

Leyden, after spending the winter in London, sailed from Portsmouth on the 7th of April 1803, and soon after his arrival at Madras, was attached as surgeon and naturalist to the commission for surveying the districts of the Mysore. In this latter capacity he was expected to turn his attention, not only to the natural history of the country, but to the manners, institutions, and language of the inhabitants. His labours hurting his constitution, obliged him to remove to Prince of Wales Island. Here he was befriended by the governor, Mr Dundas, and here, too, he procured the chief materials of the *Essay on the Languages and Literature of the Indo-Chinese Nations*, contained in the 10th volume of the *Asiatic Researches*.

He removed in 1806 from Prince of Wales Island to Calcutta, where, through the favour of the governor-general, Lord Minto, he was appointed one of the professors in the Bengal College, but was soon transferred to the office of Judge of the Twenty-four Pergunnahs of Calcutta. In 1809 he was appointed a Commissioner of the Court of Requests in Calcutta; and, in the end of the following year, having resigned this office, he obtained the office of Assay Master of the Mint. Soon afterwards, he accompanied Lord Minto upon the expedition to Java, for the purpose of collecting information touching the learning and institutions of the native tribes, and assisting the governor-general in negotiating with the local authorities, and in adjusting the future government of the country. After the British troops took possession of the city of Batavia, he caught fever from having ventured rashly into an ill-aired library, supposed to contain many Indian manuscripts, and died on the 21st of August 1811, after an illness of three days.

Shortly after Leyden's death, Lord Minto and Sir John Malcolm both publicly expressed their high estimation of

Leyden,
John.

Leyte
||
Libanius.

his extensive erudition, his unwearied pursuit after knowledge, and his exemption from all sordid vices. A few personal foibles, such as his egotism and awkward deportment, did not render him less endearing to his friends. His *Poetical Remains* were published in 1819, with a memoir by the Rev. James Morton; and in 1826 appeared his posthumous work, entitled, *Memoirs of the Emperor Baber*. An *Essay on the Life of Leyden* is contained in *Scott's Miscellaneous Works*.

LEYTE, an island of Australasia, one of the S. Philippines, between Bohol and Samar, 180 miles in length from N. to S., by 40 miles in breadth. Its surface is mountainous, and subject to volcanic action; but the soil is rich, and the climate fine for so low a latitude. The products comprise, of minerals,—sulphur, iron, and asbest; and of vegetables,—bananas, tobacco, sugar, palm-oil, and fine woods. There are also large quantities of horns, tortoise-shell, hides, and wax, exported to Europe and the United States. Pop. about 100,000, of whom nearly 70,000 are under Spanish control. See also PHILIPPINES.

LHUYD, EDWARD, a celebrated antiquary, was the son of Charles Lhuyd, Esq. of Lhanvorde, Shropshire, the descendant of an ancient Welsh family, and was born in Wales about 1670. Having entered Jesus College, Oxford, in 1687, he applied himself to the study of natural history, and particularly of fossils, under Dr Plot, whom he succeeded, in 1690, as keeper of the Ashmolean Museum. He took his degree of Master of Arts in 1701. Bent upon discovering the antiquities of the primitive Britons, he made several journeys through Wales, Cornwall, Scotland, Ireland, and Basse-Bretagne, perusing old manuscripts, transcribing the ancient charters of monasteries, and, in addition to the particular information he desired, collecting many curious notes on natural history, and other subjects, which were afterwards inserted in the *Philosophical Transactions*. Many of his researches concerning Wales were inserted by Bishop Gibson, in his edition of Camden's *Britannia*. The great mass, however, of his discoveries was published at Oxford in 1707, under the title of *Archæologia Britannica*, an account of the language, histories, and customs of the original inhabitants of Great Britain, which contains an *Irish-English Dictionary*, the outline of a larger one which he left in manuscript. His work *Lithophylacii Britannici Ichnographia*, was published at London in 1699, and reprinted by Mr Huddesford in 1760. Lhuyd died in 1709.

LIBANIUS, a celebrated sophist and rhetorician, was born at Antioch in Syria, in A.D. 314. After receiving his elementary education in his native city, he repaired to Athens, and while under the public tuition of several eminent masters, cultivated in private a taste for the classical writers of Greece. Leaving Athens, after a stay of four years, he travelled about for a short time, and finally settled in Constantinople, where his fame as a teacher of rhetoric attracting great numbers of students, drew upon him the envy and malice of the public professors. Through their influence with the Prefect Limenius, he was expelled from the city, and removed to Nicomedeia about A.D. 346. Here his great success in teaching, coupled, no doubt, with the native vanity of his character, was once more the cause of great hatred in his rivals. Driven by a plague from Nicomedeia, he returned to Constantinople, and lived there harassed by the enmities of his fellow sophists, yet refusing to leave it upon the offer of the chair of Rhetoric at Athens, until his declining health forced him to retire to his native Antioch. In his latter days, he was honoured with the notice of the Emperors Julian, Valens, and Theodosius. Chrysostom, and probably St Basil, were his pupils in eloquence; and towards these, as well as other Christians, his own paganism did not prevent him exercising tolerance. He died at some period after A.D. 391. A suc-

Libanius
||
Libel.

cessful imitator of Demosthenes and the ancient orators, he excelled all the rhetoricians of the fourth century; but his excellence in refining his diction is often attained by the loss of strength and precision of thought.

Of the extant works of Libanius there is no complete edition. The best edition of his *Προγυμνασμάτων παραδείγματα* (Examples for Rhetorical Exercises), his *Λόγοι* (Orations), and his *Μελέται* (Declamations), was published by J. J. Reiske, Leipsic, 1791–97. The best edition of his *Ἐπιστολαί* (Epistles) is by J. C. Wolf, Amsterdam, 1738. Prefixed to Reiske's edition is an autobiography of Libanius.

LIBANUS, or LEBANON. See SYRIA.

LIBAU, a Baltic seaport-town of Russia, government of Courland, at the mouth of a cognominal stream, 54 miles N. of Memel; N. Lat. 56.30., E. Long. 20.58. It is surrounded with walls, but its streets are irregular and ill paved. The houses have generally but one storey, and are constructed of wood. The chief public buildings are,—an hospital, an orphan asylum, and three Protestant and one Catholic church. The trade of the port is considerable, embracing the products of Courland, such as flax, hemp, grain, leather, and timber, which are exported to Western Europe in large quantities; and including as imports, coal, salt, sugar, machinery, herrings, and wine, sent hither chiefly from Britain and America. The harbour of Libau is formed by a lagoon, with only 12 feet of water at the bar, which obliges large vessels to anchor in the roadstead about two miles from the town, and receive their cargoes by means of lighters. The total value of imports into this town amounted in 1851 to L.25,563, and in 1852 to L.21,800; while the total value of exports in 1851 amounted to L.165,750, and in 1852 to L.142,034. Of the latter, goods to the value of L.8291 were shipped coastwise in sixty-three vessels. Pop. (1852) 8961.

LIBEL, a word which has many different meanings, but is chiefly known in this country as the name of a department of the law, which, from incidental circumstances, has come to include the naturally distinct heads, of written slander, sedition, and outrage against religion. Towards all its separate and sometimes trivial meanings, the word may be traced through history and usage from its original meaning of a little book (*libellus*) consisting of a set of leaves stitched together, and thus distinguished from a roll, or *liber*, as we distinguish a pamphlet from a volume at the present day. Certain accusatory pleadings in the courts of justice were, in Roman practice, presented in stitched leaves, which were called *libelli accusatorii*; and it is from this original use as a document, containing an accusation, that the word libel has wandered into all its wide and varied significations. After it had acquired its well known signification as a transgression of the law, it continued to retain its original technical meaning as a part of the form of process in the various systems of law derived from Rome. In the practice of the Vatican, Du Cange finds *libellus anathematis* as the equivalent to a bull of excommunication. In English ecclesiastical practice the complainant's grounds of complaint, or accusation, are set forth in a libel systematically divided into three parts. 1. The major proposition, which shows a just cause of the petition; 2. The narration or minor proposition; 3. The conclusion, or conclusive petition, which conjoins both propositions. The accusation or indictment by which in Scotland a person is accused of a crime before a court of criminal justice, is in the same syllogistic form—derived from the practice of the scholastic divines, and is called a *Libel*. The term is of frequent use in a like sense in the Presbyterian ecclesiastical courts of Scotland. It is there employed as a verb as well as a substantive; and when one is "libelled" in a presbytery, it is not meant that some rash or malicious charge has been levelled against him, but that he has been subjected to a formal accusation.

Libel.

It is this use of the word *libellus* to mean especially a document of accusation, that has made it the root of the whole law of libel. It acquired its modern meaning of a rash or malicious accusation early in the history of the Roman law, where we find the authors of *libelli famosi* visited by heavy punishments, sometimes with death. But we have few lights on the nature of the libel law of Rome, probably from the rare occurrence and limited importance of an offence which required the art of printing to give it a great social influence. The 36th title of the ninth book of the Justinian *Code* is devoted to *libelli famosi*, and refers to them rather as writings hidden in private places, for the purpose of creating an under-current of suspicion difficult to be refuted, than as accusations deriving their mischief from their publicity. The person who finds such a libel—called a *chartula*—and does not burn or destroy it, but, on the other hand, mentions its contents to some one, becomes as guilty as if he had been the author of the libel. In the tenth title of the 47th book of the Pandects, *De Injuriis et Famosis Libellis*, there are remedies for a variety of petty injuries. Among these, unjust attacks on reputation are mixed up, in a manner that would seem at the present day very incongruous, with such offences as trespasses, the unjustifiable castigation of slaves belonging to other people, assaults by slaves on each other, the interruption of public rights, sharp or oppressive practice against poor debtors, sending smoke or filth into a neighbour's house, and the like,—an incongruous and unconnected gathering of incidental matters which appear not to have found any place in the great divisions of the law. Among these injuries for which there is prætorian redress, is included the bringing disgrace or ridicule on a citizen by contumelious action, or the handing to a ruler or other influential person a *libellus* containing an attack on a citizen's good fame.

These scattered morsels of law served as precedents in the countries which adopted the Roman system. The suppression of *libelles defamatoires* is a frequent object of the old French ordonnances. The laws on the subject increased in number and precision in the sixteenth century, when the rapid progress of the art of printing made work for them. Indeed, it is generally observed by the French jurists, that until this period the maxims of the Roman law on defamatory libels had lain dormant. But from the days of Calvin downwards France has been the theatre of a relentless struggle, in which a press, restless and audacious—too often at the same time profligate—has fought with a succession of repressive laws, varying according to the various powers which have from time to time held absolute rule in that country. The French jurists notice, from an early period, how the laws for the suppression of libels cannot fail to be an irksome restraint on the genius of those authors whose strength lies in sarcasm, and greatly to curtail the enjoyment of those whose chief solace it is to read witty and epigrammatic remarks on the vices or follies of their fellow men. All who are accustomed to the perusal of that vast series of works of genius coming under the general term of *memoires*, must be conscious how little would remain behind, if, even in the periods of the strongest and most suppressive governments, all that is with us called libellous matter were suppressed. The vehemence with which those who were themselves not inclined to speak gently of their opponents or rivals, sought the aid of the arbitrary laws against libel, is very instructive. Voltaire was noted for his attempts to obtain legal redress for sarcasms on himself which were but a faint imitation of those which he had launched against others. How entirely the machinery for the punishment of libels was in the hands of those who had great personal influence, is shown by a curious anecdote narrated by Marmontel in his life of himself. He was charged with libelling, in the *Mercur*, an influential courtier, who prevailed on Choiseul, the prime minister, to commit

him to the Bastille. Marmontel says he proved his innocence to the complete satisfaction of Choiseul, who regretted what had occurred, but said he must keep his word to his distinguished friend, to whom he had pledged his faith that Marmontel should go to the Bastille; and Marmontel submitted to his fate as a necessity, expressing his gratitude for the comfortable accommodation and the luxurious table by which his prison life was alleviated.

The course of events through which the law of libel which we have seen to be a creature of the Roman jurisprudence, found its way into the common law of England, where every gift from that quarter was eyed with suspicion, forms a curious little episode in constitutional history. Offences against religion were tried in the ecclesiastical courts, which took their form of procedure from the civil law. As they became unnerved after the Reformation, the notorious Star Chamber took up their functions, adding to them a jurisdiction in minor political offences. The Star Chamber thus became the tribunal where both branches of the public law of libel were adjudged upon the Roman system. As its power waxed strong in the reign of Charles I., its political functions in administering the law of libel became more conspicuous, attracting at length a degree of public indignation before which this growing fabric of arbitrary judicial power finally fell. It was here that Prynne was condemned to the loss of his ears, and the pillory, for a collocation in the index of an unreadable volume, which seemed to point with scorn to the gaities of the queen; and that he was a second time condemned, after his ears were more closely shaven, to be pilloried with Burton and Bastwick.

On the fall of the Star Chamber this branch of jurisdiction, along with its foreign name, was, with much adroitness, appropriated by the courts of common law. To give a remedy in a court of law to a person who was slandered and maligned, and even to one who was needlessly held up to contempt or scorn, was a simple and natural process. From this point a step onward was taken by the public prosecution of those who maligned or insulted their neighbours, on the ground that the sense of injury sustained by those who suffered from their accusations, was likely to lead to excitement and turbulence. The circle of offences thus created widened indefinitely. Censorious remarks on the people who governed the country, or on the system of government itself, or the national religion, were to be punished, not as in themselves wrong, but as acts which, by the provocation which they were calculated to excite, led to a breach of the peace. The process of reasoning by which the law for the protection of private character was made a means of punishing state offences, cannot be better explained than in the words of Sir Edward Coke:—"Every label (which is called *famosus libellus*, or *infamatoria scriptura*) is made either against a private man, or against a magistrate or public person. If it be against a private man, it deserves a severe punishment; for although the libel be made against one, yet it incites all those of the same family, kindred, or society to revenge, and so tends *per consequence* to quarrels and breach of the peace, and may be the cause of shedding of blood, and of great inconvenience. If it be against a magistrate or other public person it is a greater offence, for it concerns not only the breach of the peace, but also the scandal of government; for what greater scandal of government can there be than to have corrupt or wicked magistrates to be appointed and constituted by the king to govern his subjects under him? and greater imputation to the state cannot be, than to suffer such corrupt men to sit in the sacred seat of justice, or to have any meddling in, or concerning, the administration of justice.

"Although the private man or magistrate be dead at the time of the making of the libel, yet it is punishable; for, in the one case, it stirs up others of the same family, blood,

Libel.

Libel. or society to revenge, and to break the peace; and, in the other, the libeller traduces and slanders the state and government which dies not." (The case *De Libellis Famosis*, Rep. iii. 254.)

When these doctrines were promulgated, the growing fiction of law had not so far ripened as to be applicable to pure enunciations of opinion on politics or religion. Strong expressions of political opinions, offensive to the government, were generally punished under the laws of high treason, as in the instance of Algernon Sidney, against whom the doctrines expressed in a manuscript paper found in his repositories, was the most effective evidence; and expressions deemed offensive to religion, if they were not reached by the statutes passed for the special protection of the Church of England, might be counted blasphemy, and so punished at common law. (See *BLASPHEMY*.) In the earlier cases in which the comparatively new law of libel was applied to public offences, it always rested on the statement at least of some private person having suffered an injury; and in the case of Sir Charles Smedley, prosecuted for one of the brutal acts of public profligacy for which the courtiers of Charles II.'s reign were notorious, some commentators have been at pains to show that there was an actual assault caused by his indecent exhibition, and that it was for having given occasion to that assault—not for the vague offence of outraging public decorum—that he was punished.

It was not until the case of Curl in 1728, that the fiction of the attack being made on some person, and therefore dangerous to the state, as an incentive to a breach of the peace, appears to have been dropped as tending to hamper the law. The prosecution in that case was for the publication of an indecent book, *quendam turpem iniquum et obscenum libellum*, tending to corrupt the subjects of the realm. It was not the act in itself as immoral, but its tendency "to disturb the civil order of society," that was the ultimate reason for awarding punishment, which in this instance was the pillory. But there was still a difference of opinion on the bench on the competency of the common law to reach such cases, and Justice Fortescue said,—“I own this is a great offence, but I know of no law by which we can punish it. Common law is common usage, and where there is no law there can be no transgression. At common law, drunkenness and cursing or swearing were not punishable, and yet I do not find the spiritual court took notice of them. This is but a general solicitation of chastity, and not indictable.” (Strange's *Reports*, ii., 789.)

In this manner the law of libel came to comprehend a vast range of legal remedies, from the punishment inflicted on the public offender whose acts bordered on high treason, to the damages incurred for mere personal slander. The different degrees of the offence were in some measure classified by the form of procedure. A public libel might be prosecuted on indictment presented by a grand jury, or on official information by the Attorney-General. In other cases where the private wrong was maintained to be of a public and flagitious character, the nominal concurrence of the crown with the private prosecutor was obtained in the shape of an information by the master in the crown office in the Court of King's Bench. The two classes of actions,—the one really or nominally for a public offence, the other a mere action of damages for private injury,—came to be distinguished from each other in the important feature, whether the truth of the statement was or was not a vindication. It was held that in private actions the truth of the charges made in the published document complained of, might be proved for the purpose of showing that the prosecutor had suffered no harm, and was entitled to no damages. But in proceedings by indictment or information, evidence of the truth could not be received, because it could not affect the question professedly at issue, whether the publication was

calculated to create a breach of the peace? And, indeed, it was a common exercise of jurisprudential ingenuity to maintain the paradox,—that the truth of the statements could be nothing but an aggravation of the libel, since the person who could not defend his character by the general good opinion of his fellow-citizens, or by a civil action, was all the more likely to punish his assailant by violence. The effect of such doctrines was, however, so far restrained in practice, that the Court of King's Bench would not, in the general case, grant an information for a libel to a person using that form of procedure in a prosecution virtually private, unless he made affidavit that he was innocent of the charge imputed to him.

A noted peculiarity of the English law of libel is its vagueness and uncertainty. Except from the very flagrancy of the matter, no one can tell whether certain expressions are or are not libellous, whether in a political or a private sense. It has thus been an arena in which the party for the time in power has used its strength in conflict with the party in opposition, and in which, sometimes, a popular opposition has found means of striking a blow against adherents of the government. This dubiety is in itself certainly an evil; but the great range which the law of libel takes in this country, is owing to one of the most valuable safeguards of the liberty of the press—the absence of a censorship. In countries where this restraint exists, the institution corresponding to our law of libel may occupy very narrow limits. If a work be published without the authority of the royal licenser, the presumption is against it; if it have received an *imprimatur*, its innocence is already pronounced. It was the total absence of even a modified restraint of this character that made De Lolme search among the English law books for those laws which secured the liberty of the press, and feel puzzled by the discovery that the whole department was a blank. The censorship existed of old in this country as well as others, and its disappearance is materially connected with the history of the law of libel; hence the evils of this law have, in a great measure, been the compensation paid by the public for a relief from the greater evils of the licensing system.

When the power of the printing press became first manifest as a political engine, the various governments and powers throughout Europe seemed to think that it was as much their own, and as little to be freely used by individual citizens, as the military force. The freedom to print such works as the established government might not object to, was deemed rather a concession than a restraint. In the eighteenth century, even the authors of the *Dictionnaire de Travaux*, speak of it as an important element of superiority, that the Christian states license the printing of books, while in the Mohammedan they are not licensed but prohibited. The licensing power as a prerogative in the monarch was broken up in various ways in the European states. The ecclesiastical order claimed its own share for the papal hierarchy. Licensing powers were deputed to universities and other corporations; and in countries like France, and the larger German states, works on science, or otherwise disconnected with politics or divinity, thus obtained a virtual exemption from minute examination. Censorship of the press exists to a greater or less degree in nearly all the European states. Its history in the British Empire is instructive. That printing ought to be exercised under the control and by the direction of the government, seems no more to have been doubted in England in the sixteenth century than in Spain or Austria. By the Reformation, the command of the press was more strongly concentrated in the crown of England than in that of any other kingdom, because it ceased to be divided,—the portion which belonged to the popedom, vesting, as part of his ecclesiastical supremacy, in Henry VIII. The Bible and other religious books were printed under letters patent. The use of print-

Libel

Libel.

ing presses was limited to the Company of Stationers, who were the servants of the government, subjected to strict regulation in the Star Chamber. "These regulations," says Hallam, "not only limited the number of presses and of men who should be employed on them, but subjected new publications to the previous inspection of a licenser" (*Const. Hist.* ch. xiii.). Even the *Histrionastix*, for which Prynne suffered, had been licensed; and it seemed to aggravate the wrath of the authorities, that, by his pertinacity in ever increasing the bulk of the unreadable mass as he sent it up to be licensed, Laud's chaplain, whose duty it was to examine it, permitted it, in despair, to pass without perusal. During the civil war there was a luxuriant profusion of controversial pamphlets; for either side launched the artillery of its press, as it employed its other forces, against its adversary. The Long Parliament did not scruple, by stern ordinances, to suppress dissent from its authority in the press within its reach. Immediately after the Restoration, the censorship of the press was established by a memorable statute. The act "for preventing abuses in printing seditious, treasonable, and unlicensed books and pamphlets, and for regulating of printing and of printing presses," commences with the preamble, "Whereas the well government and regulating of printers and printing presses, is matter of public care and of great concernment, especially considering that by the general licentiousness of late times, many evil disposed persons have been encouraged to print and sell heretical, schismatical, blasphemous, seditious, and treasonable books, pamphlets, and papers, and still do continue such their unlawful and exorbitant practice, to the high dishonour of Almighty God, the endangering the peace of these kingdoms, and raising a disaffection to his most excellent majesty and his government; for prevention whereof no surer means can be advised than by reducing and limiting the number of printing presses, and by ordering and settling the said art or mystery of printing by act of parliament." The act, though long and intricate, gives its essence in the short clause which provides that no private person shall print a book or pamphlet unless it be entered in the Register of the Stationers' Company; and "unless the same book and pamphlet, and also, all and every the titles, epistles, prefaces, proems, preambles, introductions, tables, dedications, and other matters and things thereunto annexed, or therewith to be imprinted, shall be first lawfully licensed and authorized to be printed by such person and persons only as shall be constituted and appointed to license the same." This is followed by a classification of literature according to the licensers. At the head come "books concerning the common laws of this realm," which are placed under the Lord Chancellor, or the other heads of the law in the order of their rank. Books of history, the affairs of the realm, or matters of state generally, are to be licensed under the authority of the Secretary of State. The next class in the order of importance contains books of heraldry, which are to be licensed by the Earl Marshall or the Kings-at-Arms. Last in order are "all other books to be imprinted or reprinted, whether of divinity, physic, philosophy, or whatsoever other science or art," to be licensed by the Primate or the Bishop of London, or by one of the universities if the printing were to be at the university press. The chief licenser appointed under the act was Roger L'Estrange, himself a celebrated pamphleteer and libeller. At the revolution he was, of course, superseded by a supporter of the new settlement. For the protection of that settlement, however, the House of Commons, ever on the watch for the promulgators of counter-revolutionary opinions, whom it punished for breach of privilege, was a better champion than any licenser; and at length the zeal and rivalry of the House in the performance of this function drove the licenser out of the field. In the year 1693 the office was held by Edmund Bohun. He was a Tory and High

Churchman, but had argued himself, or professed to have argued himself, into a thorough support of the new dynasty, on the very peculiar ground that King William and Queen Mary were entitled to the throne by right of conquest. Charles Blount, an unscrupulous author, who hated him, laid a trap to ensnare him by means of his eccentric politics, and laid before him as licenser, a work called *William and Mary Conquerors*. It was cleverly adjusted so as not to be too flagrant for the licenser's sympathies, and yet to be flagrant enough to excite the revolution party to fury. The wrath of the House of Commons fell on Blount, and on his office. The licensing act was a temporary measure, renewable from time to time, and when the bill came up for renewal, two years afterwards, the Commons, by a special vote, struck it out of the list of the temporary acts to be continued. In a conference with the Lords, who desired to renew the act, they gave in a paper containing the reasons for their vote. "This paper," says Mr Macaulay, "completely vindicates the resolution to which the Commons had come. But it proves, at the same time, that they knew not what they were doing—what a revolution they were making—what a power they were calling into existence. They pointed out concisely, clearly, forcibly, and sometimes with a grave irony which is not unbecoming, the absurdities and iniquities of the statute which was about to expire. But all their objections will be found to relate to matters of detail. On the great question of principle—in the question whether the liberty of unlicensed printing be, on the whole, a blessing or a curse to society—not a word is said." The only vestiges now remaining of restraints on the press are the obligation on every printer to put his name on his book, an arrangement advocated by Milton in his plea for a free press; and the obligation on the proprietors of newspapers to register themselves, and to give bond for the payment of any penalties to which they may become amenable.

At several periods, and especially during the anti-revolutionary fervour created by events in France, the liberty of the press was threatened, and temporarily affected. The general principle, however, outlived all these dangers, and it was felt that in the present reign the law of libel might be safely stripped of some of its asperities. The law was regulated in 1843, by an act professing to be passed "for the better protection of private character, and for more effectually securing the liberty of the press" (6th & 7th Vict., c. 96). It gives weight to any apology or reparation which the utterer of a libel may have offered, and particularly, when it has appeared in a newspaper, to an apology published in the same manner. Libel had been excepted from those actions in which the defendant might pay into court the damages tendered by him; but by this act, when the absence of malice, and the publication of an apology are pleaded, the defendant may tender damages. On an indictment or information, the defendant is authorized to enter a general plea of not guilty; and it will be justified if he prove the truth of his statements, and that it was for the public benefit that they should have been published. This neutralizes the old principle, which refused to admit evidence of the truth when the trial was on indictment or information. As a partial protection to the editors of newspapers, the defendant might prove that the publication was made without his consent or knowledge. The act does not extend to Scotland; it was extended to Ireland in 1845.

In Scotland, the word libel, though used, as we have seen, to express a formal accusation, in the practice of the courts of law, was not indigenous in the sense in which it has been chiefly used in England. The law equivalent to that of political libel was, until lately, in a very unsatisfactory condition. Of old, it was called leasing-making, as the crime of falsely representing the conduct of governors towards the people. After the Union, this vernacular term dropped

Libel.

Liberia. out of use, and the nomenclature of the civil law supplied the word sedition in its stead. In the years 1793 and 1794, the vague character of the law enabled the government to carry out, in Scotland, severities which the strict barriers protecting the freedom of the subject at once checked in England. The punishments at that time inflicted on men, some of whom were merely pursuing such a course of free criticism on the practical condition of the constitution as all parties have in later times practised and encouraged, has received a general condemnation, which renders it unnecessary to recal the particulars of the several cases. Their most offensive feature was this, that sentences of transportation to the penal colony of New South Wales were passed, avowedly in the administration of old laws, adopted when Scotland had no colonies, and when transportation was impossible, although they doubtless sanctioned banishment, or the driving of the culprit out of the country. This vague character of the law, which, in a time of terror and excitement, had shown itself so liable to abuse, was corrected by statutes which imposed fine and imprisonment as the punishments of sedition.

Fortunately, of late years, the law of political libel has dwindled almost out of existence, as a disease in the vital frame disappears before progressive health and vitality. The reverberations of the great continental revolutions of 1848 did not pass over Britain without commotion; but the safety of the country was sufficiently secured by suppressing acts of violence without too curious an inquiry into the tendency of opinions. As to the law of private libel, both in England, where it grew, and in Scotland, to which jury trial virtually transplanted it, the width and vagueness of its character are the objects of continued complaint. Perhaps a means may be some day found of correcting this defect; but in the meantime, it must be viewed as the price paid for the liberty of the press and for freedom of discussion generally. It is quite true, that no lawyer can give a definition of libel as he can of theft or forgery; that, according to the general descriptions of a libel supplied by the law-books and the cases, there are many people every day unconsciously committing the offence; and that there are multitudes of whom it may be said, that they owe it not to their keeping within the law, but to the forbearance of their fellow-citizens, and that freedom from vindictiveness so honourable to the British character, that they are not attacked with prosecutions. But the answer to all this is, that the reliance is well bestowed. Every man is in the hands of the public, and in the long run they see fair dealing.

(J. H. B.)

LIBERIA, a free negro republic on the W. coast of Africa, extending in a S.E. direction from Sierra Leone, along the coast for about 500 miles, and having an average breadth of about 40 miles; between N. Lat. 4. 20. and 7. 20., W. Long. 6. 50. and 12. 40. Area about 20,000 square miles.

The republic of Liberia owes its existence mainly to the efforts of a few benevolent citizens of Washington, who, in 1816, formed themselves into a society called the "American Colonization Society," for the purpose of rescuing the free people of colour from the degradation and misery to which they were condemned in America. In 1817 a deputation of the society visited England, and was received with much cordiality by Wilberforce, and other friends of the anti-slavery movement; and with their advice the agent of the society was sent out to the W. coast of Africa for the purpose of making a careful survey of the country, and reporting as to its suitability for a negro colony. The site first chosen was the small island of Sherboro, situated near the coast, about 120 miles S. of Sierra Leone, and the first colonists arrived there in the early part of 1820. The situation, a low, densely-wooded island, proved unhealthy in the extreme, so that in the course of a few months most of the agents who attended the expedition, and many of

the negroes, fell victims. A less deadly climate had, therefore, to be sought for, and an agent was again sent out by the society for that purpose. Cape Mesurado, on the mainland, about 300 miles S.E. of Sierra Leone, and rising about 150 feet above the general level of the shore, seemed to promise a suitable locality for the settlement. With difficulty the native chiefs were induced to dispose of a tract of land here; and on the 25th of April, 1822, the American flag was planted on Cape Mesurado; the settlers of Sherboro, who had been removed for a time to Sierra Leone, having been transferred to their new settlement. Their numbers were speedily augmented by fresh arrivals, but the colony was long in a very precarious and unsatisfactory condition. The settlers lived in continual fear of the fierce and treacherous tribes by whom they were surrounded, who not unfrequently attacked them at a disadvantage and inflicted considerable loss. They were also on several occasions reduced to the greatest distress by scarcity of provisions, and a failure of ammunition; and the climate, though less fatal than formerly, still proved very injurious. By degrees, however, these difficulties were overcome, and as their numbers increased they became better able to maintain their ground against the encroachments of the neighbouring tribes. The weaker tribes now became desirous of being received under their protection, and they were in every case received on condition of their becoming Liberian citizens. Partly by this mode of annexation, and partly by the occasional purchase of small portions of territory, the boundaries of the settlement were gradually extended. New settlements were made, new towns built, trade increased, and agriculture flourished. In 1839 a constitution was framed, and a governor appointed by the Colonization Society; and in 1847 the independence of the colony was formally declared, and a republican constitution adopted. The British and French governments promptly recognized the new government, and framed liberal treaties with it. The constitution is professedly a copy of that of the United States. The executive power is vested in a president, who must be at least thirty-five years of age, have resided five years in the country, and be in possession of an income of 500 dollars. He is elected for two years, but may be indefinitely re-elected. The senate and house of representatives exercise the legislative power. The senate consists of six members, at least twenty-five years of age, having resided in the colony for three years, and possessed of an income of 200 dollars. They are chosen for four years. The representatives are chosen for two years, and are required to be twenty-three years of age, to have resided for two years in the colony, and to be possessed of an income of fifty dollars. The number of representatives is 28. The judicial power is lodged in a supreme court, and several inferior tribunals. The rights of citizenship belong exclusively to people of colour. The climate of Liberia, although more healthy than that of Sierra Leone, is still uncongenial to the white man, though to the blacks it has the character of being very genial. The effect of clearing, draining, &c., upon the climate during the last ten years, is said to be very remarkable. The duration of life among the colonists is considered to be about the same as in the United States. The country is characterized as being very fertile, the hills and plains being covered with a never-fading verdure. Cotton, coffee, indigo, and the sugar cane, are all spontaneous productions of the forests. Rice, Indian corn, Guinea corn, and numerous species of fruits, may be grown to any extent. Cattle, swine, fowl, ducks, goats, and sheep, require no care save only to keep them from straying. Palm oil, camwood, ivory, gold-dust, coffee, indigo, ginger, arrowroot, and hides, are the principal exports. Palm oil is the great staple of Liberia at present; and the demand for it in England, France, and

Liberia.

Liberius
||
Liberty of
the Press.

the United States is rapidly increasing. Coffee, sugar, and cotton would, with a due application of capital and labour, become of the greatest value to the state. A considerable coasting trade is carried on, as well as a large trade with the interior. The exports to foreign countries are said to average upwards of L.100,000 annually. Pop. estimated at about 200,000, of whom about 10,000 are free blacks from the United States. Schools and places of worship have been established over the country. Liberia is divided into the counties of Mesurado, Bassa, and Sinde. The chief town is Monrovia, containing about 2000 inhabitants.

The "Maryland Colony," on Cape Palmas, in the S.E. of Liberia, was founded in 1834, by the "State Colonization Society," and consists of free coloured emigrants sent thither from the state of Maryland. Till very recently this colony remained dependent on the parent society, but, according to the latest accounts we have received, it too had declared its independence, though it seems very doubtful if so small a republic can exist in that part of the world; and it would unquestionably be for the advantage of both it and Liberia that they were conjoined.

LIBERIUS, Bishop of Rome, succeeded Julius I. in 352, during the dominancy of the semi-Arians. Soon

after his accession, it is said, he excommunicated Athanasius, the great antagonist of Arianism; but when the councils of Arles and Milan, overawed by the Emperor Constantius, deposed that bishop in 355, Liberius, changing his policy, could not be induced, either by compulsion or blandishments, to sign the deposition. Hurried in secrecy from Rome during the night, and carried before the Emperor in Milan, he still remained faithful to Athanasius, and was banished to Bercea, in Macedonia. After an exile of two years, however, he withdrew his protest, and signed the semi-Arian creed of Sirmium. The Emperor, overcome by the pertinacious petitions of the ladies at Rome, then permitted him to share the management of his see with Felix, who had succeeded during his banishment. The latter was forced to flee from popular violence, and Liberius, left in the peaceful possession of his dignity, expiated, it is said, his defection from orthodoxy, by a sincere recantation. He died in 366.

Liberius is the reputed author of twelve epistles, published in Coustant's *Epistolæ Pontificum Romanorum*, Paris, 1721; and he is said to have built the Basilica, on the Esquiline Mount, which from him has sometimes been called Liberiana, but is now known as the Santa Maria Maggiore.

the Press.

LIBERTY OF THE PRESS.

I.—NATURE AND OBJECTS OF THE INQUIRY.

THE task of pointing out which of the acts, capable of being committed by the press, it would be expedient to prohibit under penalties, we trust will be found to be greatly diminished, by what has been already established in the articles GOVERNMENT and LAW.

There is scarcely a right, for the violation of which, scarcely an operation of government, for the disturbance of which, the press may not be employed as an instrument. The offences capable of being committed by the press are indeed nearly co-extensive with the whole field of delinquency.

It is not, however, necessary to give a separate definition of every such violation or disturbance, when committed by the press; for that would be to write the penal code a second time, first describing each offence as it appears in ordinary cases, and then describing it anew for the case in which the press is the particular instrument.

If, for the prevention of the violation of rights, it were necessary to give a separate definition, on account of every instrument which might be employed as a means of producing the several violations, the penal code would be endless. In general, the instrument or means is an immaterial circumstance. The violation itself, and the degree of alarm which may attend it, are the principal objects of consideration. If a man is put in fear of his life, and robbed of his purse, it is of no consequence whether he is threatened with a pistol or with a sword. In the definition of a theft, of a fraud, or of a murder, it is not necessary to include an account of all the sorts of means by which these injuries may be perpetrated. It is sufficient if the injury itself be accurately described. The object is to prevent the injury, not merely when produced by one sort of means or another sort of means, but by any means.

From these illustrations, it sufficiently appears, that, if an accurate penal code were composed, defining the violations of rights, and the disturbances of the operations of government, to which penalties were to be annexed, every offence capable of being committed by the press would be

defined without mentioning the press. It is no less evident, that if we include in the term *libel*, as, to the great encouragement of confusion, is generally done, all the offences capable of being committed by the press, we include in the definition of libel all the definitions of the penal code.

As far as persons and property are concerned, the general definition of the acts by which rights are liable to be violated, has always been held sufficient; and has been regarded as including not less the cases in which the instrumentality of the press has been employed, than those in which any other means have been employed to the same end. Nobody ever thought of a particular law for restraining the press on account of the cases in which it may have been rendered subservient to the perpetration of a murder or a theft. It is enough that a law is made to punish him who has been guilty of the murder or theft, whether he has employed the press or any thing else as the means for accomplishing his end.

There can be no doubt, however, that the press is an instrument peculiarly adapted for the commission of injuries against reputation, and for effecting disturbance to the operations of government, while it has no peculiar adaptation for the commission of other offences. Here, too, there is the greatest disposition to restrain the press within improper limits. It is demanded of us, therefore, upon this part of the subject, to enter into greater detail.

We are then to inquire, in the first place, What are the acts of the press with respect to *private reputation*; and next, What are the acts with respect to *government*, which it is desirable that punishment should be employed to restrain.

II.—OFFENCES OF THE PRESS, WITH RESPECT TO PRIVATE RIGHTS.

Agreeably to the principles which have been already considered in the article LAW, no act can be regarded as an offence with respect to an individual, which is not a violation of some of his rights.¹

¹ In the description which follows of that violation of rights which is most liable to be committed by the press, and of the mode

Liberty of the Press. In considering the rights which ought to be established with respect to reputation, one proposition may be assumed; that every man should be considered as having a right to the character which he deserves; that is, to be spoken of according to his actions.

Such Offences should be defined.

In what manner the definition of this right, which would form a part of the civil code, should be expressed, is not now the question; it is evident there is no peculiar difficulty in the matter. As words, not thoughts, are the object of legal cognizance, the right can only have respect to security against certain words; words, imputing to the individual actions which he has not performed, or a disposition to certain actions, without evidence that such a disposition exists.

Suppose that one man has instituted a suit against another, for the offence of having violated, through the press, his right to some part of the reputation which he deserves. In his ground of complaint he must affirm that the man has imputed to him either the performance of actions which he did not commit, or a disposition to certain actions, where no evidence of such disposition can be given.

The words are produced; and the first question is, whether they do or do not impute the actions which, in the complaint, or bill of accusation, they are alleged to impute?

It is to be observed, that they who oppose the attempt to define the offences, which, for shortness, we call the offences of the press, make use of such occasions as this to raise their objections. How, they ask, can all the forms of expression be defined, by which the imputation of such and such actions may be, either more openly, or more covertly, conveyed?

It is very evident that the question, on such an occasion, whether the words do or do not impute such or such actions, is a question of fact. The law says, that such and such actions shall not be imputed, defining the actions. Whether such and such a man has imputed such actions, and whether by one set of words, or another set of words, are questions of fact.

The law, when it said that such and such acts should not be imputed to a man, could not determine whether A, who is accused by B of having imputed to him one of those acts, did so or not. That is to be determined by evidence bearing upon the point. One, and in general the main article of that evidence, are the words which have been used. What is the import of these words, or, which comes to the same thing, what is the degree of proof involved in them, is to be determined, as all questions respecting the weight of evidence are, in each instance, to be determined, by the tribunal before which the accusation is brought. The interpretation of words rests upon the same footing in this, as in all other cases, that, for example, of a will. The law determines, that whatsoever disposition a man has made with respect to his property, shall take effect after his death. But whether A has left his manor of Dale to B, is a matter of fact to be determined by evidence applying to that particular point; principally by that arising from the words of the will.

It may still be argued, by persons who do not easily renounce an opinion to which they have once given their support, that the actions, the imputation of which, the legislature means to prohibit, cannot be defined.

But this is a position which cannot long be maintained.

It is hurtful to a man, if he is believed to have committed some actions, or to have a disposition to commit them; it is not hurtful in the case of others. Evidently it

is by imputation of the first sort alone, that any right with respect to reputation can be infringed. *Liberty of the Press.*

The acts which a man receives injury from being believed to have committed, or to be disposed to commit, are either those to which the law has annexed penalties, or those to which the penalties of public disrepute and dislike are annexed.

With respect to those acts to which the law has annexed penalties, as theft, murder, perjury, and so on, it will not be pretended that there is any difficulty; the law has already defined them, or ought to define them, and they may be marked with perfect precision by a few words.

Those acts which it is hurtful to a man, solely on account of the disrepute and dislike which they produce, to have it believed that he has committed them, may also be with sufficient accuracy determined.

Compensation should be made to the Individual for Injuries sustained by Offences of the Press.

The ends to be attained by punishment are, Reparation to the individual to whom injury has been done, and Prevention of similar acts in future.

In the idea of all punishment, effectual reparation to the injured individual is a necessary and essential ingredient. Suppose, then, it were declared by the legislature that every imputation to a man of acts which bring the evil of dislike and disrepute upon him who has committed them, that is, every false imputation, shall be punished at least by reparation to be made to the party injured; the term *evil* is to this purpose perfectly precise. It would remain with the complainant to show what kind and degree of injury he had received; which is a matter of fact, to be estimated, in each instance, from the evidence adduced, by the tribunal before which the question is brought. If the injury sustained is a pecuniary injury, the question coincides exactly with the question of damages, decided regularly, in English courts, as a question of fact, by the jury.

Injuries of the kind which we are now considering can affect a man only in two ways; either by lessening the pecuniary value which he might otherwise have enjoyed, or by lessening the marks of respect and affection which he would otherwise have received. What the loss is, in this latter instance, is also evidently a question of fact. It has nothing, therefore, to do with the legal definition of the offence, the business of the legislature. It is a question, which, like other questions of fact, must of necessity be determined upon evidence by the tribunal before which it is brought. It is no doubt a question of delicacy, and considerable difficulty, because the evidence must often consist of very fine and minute circumstances, which can seldom be precisely ascertained. But this is not the only class of judicial questions, the determination of which depends upon such evidence as it is very difficult accurately to collect and to weigh. What is of greatest importance, on this occasion, to remark, is, that all the difficulty lies in the matter of fact. There is no doubt or obscurity in the law, which says, that whatsoever hurt a man has sustained through actions or dispositions falsely imputed to him, he shall receive compensation for. Difficulties, however, arising either from the complexity of the matter of fact, or the obscurity of the evidence, no legislative enactments can prevent. These are confided to the skill and integrity of the judge.

The compensation which ought to be made to a man for the diminution of those marks of respect and affection which he would otherwise have received, is a question for

Liberty of
the Press.

the legislature. Let us suppose that a soldier has been accused of cowardice, in such a manner as to create a general belief of the truth of the accusation; that a man of honour has been accused of mendacity, or of some of those irregular propensities to which the horror of the public is attached; it is evident that money is not, in such cases, an appropriate compensation.

When a man, through the offence of another, has been deprived of a certain amount of money, or of money's worth, we say that he has received compensation, when he is placed in the same situation in which he would have been if the offence had never taken place.

According to this idea of compensation, a man, against whom an unfavourable opinion has been created by the act of another man, has received compensation, when he is placed in the same situation with regard to the opinion of those with whom he is connected, as if that act had not taken place. This, therefore, is the object which it ought to be the endeavour of the legislature to effect.

One expedient is perfectly appropriate. It is, that the man who has falsely propagated an unfavourable opinion with respect to another, should be made to do whatever is in his power to remove the impression he has made. To this end, he should publish the sentence of the judge, declaring that the action or disposition which he had imputed to the individual injured, he had imputed to him falsely. He should at least be made to publish it in every way in which he had published the imputation. Frequently a more extensive publication might be required.

In some cases, it will be allowed, that thus much would suffice. It may, however, be affirmed, that often the impression would be too profoundly struck, to be effaced by a mere knowledge of the sentence of the judge. In such cases, something more in the way of compensation would be required. On this, it is of importance to be observed, that if the impression produced by an imputation, which, after solemn inquiry, the judge has declared to be false, should not, by that declaration, be completely effaced, it implies necessarily one of two things; either that the public have evidence of the truth of the accusation, which was not adduced to the judge, and then the remaining impression is not owing to the imputation which the judge has condemned, but to the evidence; or, secondly, that the public mind is in a state of gross ignorance and imbecility, capable of forming opinions, even on the clearest subjects, not only not according to evidence, but in opposition to it. If the public mind, however, is in such a deplorable condition, it is the fault of the legislature; and for the rectification of this evil, the best course undoubtedly is, to take effectual measures for the instruction of the people, which instruction would soon place them beyond the danger of such delusions. In the mean time, if something more than the publication of the sentence of the judge were necessary to restore a man to that degree of consideration, of which the false imputation had deprived him, governments have numerous ways of raising the consequence of individuals; and no legislature would be at a loss for a gradation of expedients suited to the scale of demand.

Means which should be used for preventing the Violation of Rights by the Press.

We have now illustrated that part of this question which regards compensation to the injured individual. It remains to inquire what is best to be done in this case, for the attainment of the other object of punishment, namely, the prevention of similar offences in time to come.

To devise a punishment sufficient to prevent an offence, is to provide a motive sufficient to counteract the motive which leads to the offence. We have hence to consider

Liberty of
the Press.

what are the motives by which men are incited to make false imputations on the characters of others.

These motives may be of three different sorts. A man may derive *pecuniary profit*, he may derive *comparative distinction*, or he may satisfy his desire of *vengeance* by blackening the character of his neighbour.

In the case in which a man has by calumny wrongfully intercepted the pecuniary receipts of his neighbour, the obligation of making satisfaction to the party injured would, it is obvious, alone suffice, provided the machinery of the laws were sufficiently perfect to render the execution of them certain. Seldom would any man calumniate his neighbour for the sake of placing £20 in his own pocket, if he were sure that, next day, or next week, he would have to restore it, with all the profit which might have been made by the use of it, and with the disgrace besides of having committed an action which other men abhor.

Sometimes, however, a man may derive pecuniary profit from calumniating persons whom he has not by that means deprived of any pecuniary advantage; by the sale, for example, of a slanderous publication; when the satisfaction due to the individual may not be of a nature to counteract the motive which leads to the offence. The expedient in this case, also, is sufficiently obvious, and sufficiently simple. It is necessary to ascertain the whole of the gain which has been made by the offender, and to take it away from him. This, together with the satisfaction which he ought to make to the injured individual, would, if it were certain, create a surplus of motive to abstain from the injurious act.

In both of these cases, if the execution of the law is uncertain, an additional punishment may be necessary, sufficient to compensate for the chance of escape. The allowance to be made on this score must depend upon the imperfection of the laws; while one important fact is to be kept in remembrance, that as severity of punishment, beyond a certain point, is increased, certainty of execution is diminished. The true expedient, therefore, is to render the machinery of the laws so perfect, that the penalties which they denounce may always be sure of execution; and then hardly any thing beyond compensation to the individual, and the abstraction of any additional gain which might have been made by the propagation of slander, would be necessary to repress all offences against the reputation of others, to which the motive was constituted by pecuniary gain.

The two remaining cases are still more simple. If a man propagates a falsehood, for the sake of injuring the character of a man by whom his own consideration is eclipsed, it is only when he expects to obtain by that means a permanent advantage. If he knows that immediately the law will take its hold upon him; that he will be compelled to re-elevate the character of his neighbour, and to proclaim his own disgrace, he will see that, to attempt depressing the character of another man by calumny, is the very worst of all expedients for giving a comparative elevation to his own. The same is the result in the case where vengeance constitutes the motive to injure the reputation of another. To render this proposition manifest, the most obvious illustration will suffice. No man, to gratify his malignity to another person, would kill his ox or his ass, provided he were sure that immediately he would be obliged to make him full satisfaction; and instead of injuring the man whom he hated, to injure only himself. No, the rudeness and inefficacy of the law, holding out a chance of escaping the duty of making reparation, is the sole origin and cause of all offences of this description; and if the law were placed in a state but approaching to perfection, hardly any thing beside the obligation of making satisfaction would be necessary to repress the whole of this order of crimes.

Whether any Imputation by which Truth is not violated, should be considered an Offence by the Press.

Liberty of
the Press.

Liberty of
the Press.

We have now made considerable progress in this important inquiry. We have ascertained, we think, with sufficient evidence, all that is necessary to be done for preventing injuries to the reputation of individuals; provided the rights of reputation are not, by the civil code, made to extend beyond the boundaries of truth. Whether or not they ought to extend farther, and individuals ought to be protected from the disclosure of acts which they may have committed, is, we confess, a question highly worthy of solution; upon which, therefore, before we proceed to any of the subsequent topics, we shall offer the following reflections.

There can be no doubt that the feelings of the individual may be as painful, where actions of a disreputable nature are truly, as where they are falsely, imputed to him. It is equally certain, that no painful feelings ought to be wilfully excited in any man, where no good, sufficient to overbalance that evil, is its natural consequence.

We have already shown, that reputation is injured by the imputation of acts of two different descriptions; first, those to which the law annexes penalties; secondly, those to which disrepute and the dislike of others are annexed.

With respect to those acts to which the law annexes penalties, there is no room for uncertainty or dispute. Unless the law is a bad law, which ought to be repealed (this, we confess, constitutes an exception, and one which, in very imperfect codes, extends a great way), the law ought not to be disappointed of its execution. The man who gives information against a murderer, or a thief, by the press, or without the press, renders a public service, and deserves not punishment, but reward.

It appears, therefore, that the question, whether a man ought to be protected from the imputation of actions which he has really committed, refers solely to those acts which, without being punishable by the law, are attended with disrepute; acts, in other words, which the members of the society disapprove and dislike.

The prospect of the immediate and public exposure of all acts of this description, would be a most effectual expedient to prevent their being committed. Men would obtain the habit of abstaining from them, and would feel it as little painful to abstain, as at present it is to any well educated person to keep from theft, or those acts which constitute the ill manners of the vulgar. The fable of Momus has always been understood to carry an important moral. He found grievous fault that a window had not been placed in the breast of every man, by which, not his actions alone, but his thoughts, might have been known. The magnanimity of that Roman has been highly applauded, who not only placed his residence in such a situation that his fellow-citizens might see as much as possible of his actions, but declared a wish that he could open to all eyes his breast as well as his house.

If the hatred and contempt of the people, therefore, were always rightly directed, and rightly proportioned,—if they never operated against any actions but those which were hurtful, either to the individual himself, or to others, and never, but in the degree in which they were hurtful,—the case would be clear; the advantage which would be derived from the true exposure of any man's actions of any sort, would exceed beyond calculation the attendant evil. The great difficulty of insuring the practice of morality, in those numerous and highly important cases to which the legal sanction, or the *security of pains and penalties*, does not extend, consists in the want of a motive always present, and powerful enough to counteract the instant motive which urges to the instant offence. That motive almost every man would derive from the know-

ledge that he had the eyes upon him of all those the good opinion of whom it was his interest to preserve; that no immoral act of his would escape their observation, and a proportionate share of their hatred and contempt. It is in this view that the aid of religion has been sometimes regarded as of importance to morality, suggesting the idea of a high and constant observer. All motives, however, are feeble, in proportion as the pains and pleasures upon which they depend are distant, vague, or uncertain. Divines agree with all other men in complaining of the trifling effect of religious motives upon the lives of the greater number of men. From the nature of the prospect on which these motives depend, they could not be less feeble than they have been thus described. The case is not the same with the motives arising from the sentiments which we know we shall inspire in the breasts of our fellow-creatures. It is a matter of daily and incontrovertible experience, that these are among the most powerful which operate upon the human mind. The soldier rushes upon death, and endures all the hardships and toils of his cruel profession, that he may enjoy the admiration and escape the contempt of his fellow-men. On what else is founded the greater part of all human pursuits? How few, even of those who toil at the meanest occupations, but exert themselves to have something for show, something to make an impression upon the eyes of those who surround them? The very subject of the present inquiry derives from this source the whole of its importance. The value of reputation is, indeed, but another name for the value which we attach to the favourable and unfavourable sentiments of our fellow-men.

It is, however, true, that their unfavourable sentiments do not always fall where they ought; and this, we confess, is a consideration of the highest importance. It very often happens that men's antipathies are excited to actions from which no evil ensues, either to him who performs them, or to any body else. If any man derives a pleasure from such actions, it is to limit his sphere of innocent enjoyment to debar him from them. And if the press exposes him to the antipathies, the hatred, and contempt of his fellow-creatures, on account of those actions, it produces an evil, uncompensated by the smallest portion of good. To an Indian Brahmin, if he were known to have eaten, even when starving, a morsel of food which had been prepared by a Christian, the consequences would be dreadful. Where the Roman Catholic religion is in vigour, a man who should indulge himself in animal food on forbidden days would be regarded with horror. The use of wine, however moderate, would render a Mahomedan execrable to the whole of his tribe.

This misdirection of the favourable and unfavourable sentiments of mankind; in other words, this perversion and corruption of their moral sentiments, has, in by far the greater number of instances, been the work of priests, contriving the means of increasing their influence. In some very important instances, such, for example, as the prejudices of birth, at one time in Europe so powerful as to make men of low birth objects of the greatest contempt, men of elevated birth objects of the highest veneration, the perversion of the moral sentiments is evidently the work of the aristocratical class, securing to themselves a more easy dominion over the rest of their fellow-creatures.

It is, therefore, evident, that where antipathies, religious or aristocratical, should prevail, the press would be hurtfully employed in giving notoriety to the facts which would expose a man to the operation of either.

We have now ascertained the cases in which it would not be good that men should be protected from the declaration of truth by the press, and also the cases in which it would be good that they should be so protected.

What, upon this view of the subject, would be desirable,

Liberty of
the Press

is sufficiently clear. It would be desirable that, in the one set of cases, the declaration should be allowed, in the other it should not be allowed. Are the two sets of cases, however, capable of being accurately distinguished?

If the comparison is made with any attention, it will not be difficult to determine that the evil to be incurred by the loss of truth in the set of cases in which the declaration of it would be useful, is much greater than that which would arise from permitting the declaration in the cases in which it would be hurtful.

In the first place, the set of cases in which the declaration would be useful are much more numerous, and much more important, than those in which, in any tolerably civilized state of society, it would be hurtful. Those in which it would be useful embrace the whole field of morality, all those acts, the performance of which, on account of their singular importance, has been elevated to the rank of virtues. Every body believes and proclaims, that the universal practice of the moral virtues would insure the highest measure of human happiness; no one doubts that the misery which, to so deplorable a degree, overspreads the globe, while men injure men, and, instead of helping and benefiting, supplant, defraud, mislead, pillage, and oppress one another, would thus be nearly exterminated, and something better than the dreams of the golden age would be realized upon earth. Toward the attainment of this most desirable state of things, nothing in the world is capable of contributing so much as the full exercise of truth upon all immoral actions, that is, all actions, the practice of which is calculated to lessen the amount of human happiness. According to this view, the justice of which it is impossible to dispute, the evil incurred by forbidding the declaration of truth upon all immoral actions is incalculable. That which would be incurred by the antipathies of misguided minds against actions innocent in themselves, nobody, we should imagine, would so much as think of placing in comparison.

In our own country, for example, the classes of actions which, though they injure nobody, expose a man to the unfavourable sentiments of others, are not numerous. The number of persons who would be exposed to inconvenience on account of the declaration of truth in regard to them, would be small in comparison with those who would benefit by its declaration in the case of all really hurtful acts.

It is, indeed, important to be observed, that a comparative smallness of number is necessarily implied in the supposition of injury from any unfounded antipathy. Those who share in the antipathy, of course, abstain from the action. And unless the antipathy were so general as to include almost the whole of the society, it would lose its injurious effect. Besides, all the injury which can be done to the individuals against whom truth would in this manner operate injuriously, would be, to make them abstain from the acts which were thus condemned.

Another thing to be considered is, that the whole of the evil arising from the exercise of truth is dependent upon an accidental circumstance, capable of being removed; upon a mental disease, requiring to be cured, which the legislature ought to be constantly endeavouring to cure, and toward the cure of which truth is likely to operate as the most effectual of all expedients. If any considerable inconvenience were experienced from exposure to unfounded antipathies, in consequence of the publication of truth, the groundlessness of these antipathies could not fail in this case to be so often canvassed, and made to appear, that at last it would become familiar to the multitude, and the antipathies would expire.

It clearly, therefore, appears, that, if the cases in which the declaration of truth would expose to unfounded prejudices could not be clearly defined, and separated from the cases in which the declaration would be salutary, the rule of permitting truth ought to be universal. But,

though we perceive, that, to a considerable extent, there Liberty of agreement in drawing the line of distinction between what is hurtful and what is not, we are persuaded that principles might be laid down in which all would agree, and which would serve to mark out certain cases for exception with sufficient exactness. If any such cases could be separated, either of actions, which, though injurious to nobody, excited antipathies, or of facts, as those of birth, for which, though a man was in no respect worse, he might be regarded as worse; the exercise of truth, with regard to them, might, on the express ground that they were actions innoxious, or facts which ought to be of no importance in the estimate of human worth, be forbidden, when injurious, under the penalty of at least making reparation for all the injury of which it had been the cause.

III.—OFFENCES OF THE PRESS WITH RESPECT TO GOVERNMENT.

We have now explained, we trust with sufficient clearness for the present occasion, the principles upon which laws should be constructed for protecting the *rights of individuals* against violations committed by the press. The first part of this inquiry, therefore, we must consider as completed. In the second part we have to explain the principles upon which they should be constructed for protecting the *operations of government*.

Exhortations to obstruct the Operations of Government in detail should, Exhortations to resist all the Powers of Government at once should not, be considered Offences.

Unless a door is left open to resistance of the government, in the largest sense of the word, the doctrine of passive obedience is adopted; and the consequence is, the universal prevalence of misgovernment, insuring the misery and degradation of the people. On the other hand, unless the operations of government, instituted for the protection of rights, are secured from obstruction, the security of rights, and all the advantages dependent upon the existence of government, are at an end. Between these two securities, both necessary to obtain the benefits of good government, there appears to be such a contrariety, that the one can only be obtained by the sacrifice of the other.

As this difficulty, however, arises chiefly from the extent of the terms, a close inspection of the cases which they involve, and which they have a tendency to confuse, will enable us to discover the course which it belongs to practical wisdom to pursue.

It is necessary, first of all, to ascertain what sort of obstructions are inconsistent, and what are not inconsistent, with those operations of government which are necessary for the protection of rights.

The application of physical force to resist the government in applying to the execution of the laws the physical power placed at its disposal by the law, is such an obstruction of the operations of government, as would, if frequent, render it inadequate to the ends which it is provided to secure. This application of force, therefore, must be treated as an offence; and any thing proceeding from the press, tending directly to produce it, as a similar offence.

This proposition requires to be illustrated. The application of physical force which is here described, and treated as an evil, is clearly distinguishable from that resistance of government which is the last security of the many against the misconduct of the few. This is an application of physical force to obstruct the operations of government in detail; the proceedings, for example, of a court of jus

Liberty of
the Press.

tice; the proceedings of the legislative organ, or the proceedings of any of the administrative functionaries, in the execution of the duties with which they are charged. This is not that species of resistance which is necessary, in the last resort, to secure the people against the abuse of the powers of government. This last is not a resistance to the operations of government in detail. It is a resistance to all the powers of government at once, either to withdraw them from the hands in which they have hitherto been deposited, or greatly to modify the terms upon which they are held.

Even this last species of resistance it may be necessary to punish, at least in a certain degree, whenever it is not successful; that society may not be disturbed by commotions which the majority of the people disapprove. This, however, is a question which belongs to the penal code in general, and does not concern the inquiry into the offences capable of being committed by the press; because we think it may be satisfactorily shown, that no operation of the press, however directly exhorting to this species of resistance, ought to be treated as an offence.

The reason is, that no such exhortation can have any immediate or formidable effect; can, indeed, have any effect at all, except through such mediums as ought to be at all times perfectly free. Suppose that a work is published, exhorting the people in general to take arms against the government, for the purpose of altering it against the consent of its rulers. The people cannot take arms against the government without the certainty of being immediately crushed, unless there has been already created a general consent. If this consent exists in such perfection as to want nothing to begin action but an exhortation, nothing can prevent the exhortation; and forbidding it is useless. If the consent does not exist in nearly the last degree of perfection, a mere exhortation, read in print, can have no effect which is worth regarding. In all circumstances, therefore, it is useless, and consequently absurd, to treat this species of exhortation as an offence. If, on the other hand, it were clearly recognised, that every man had a license to exhort the people to the general resistance of the government, all such exhortations would become ridiculous, unless on those rare and extreme occasions on which no prohibitions and no penalties can or ought to prevent them. The doctrine of this paragraph, which will appear somewhat startling and paradoxical to minds accustomed only to a certain train of ideas, will receive illustration, and we trust will be amply confirmed, as we proceed.

Having mentioned this as a grand exception, we now return to the cases in which not only physical force applied to obstruct the operations of government, but the publishing of exhortations to that obstruction, ought to be treated as an offence. These relate solely, as above remarked, to the operations of government in detail. Obstructions, it is evident, may be offered to the operations in detail of a government which possesses and deserves the fullest confidence of the community at large; and the press may be employed in directly and efficiently exciting to these obstructions. A hand-bill, for example, distributed at a critical moment, and operating upon an inflamed state of mind, in a narrow district, may excite a mob to disturb the proceedings of a court of justice, to obstruct public officers in the execution of their duties, or even to disturb, on this or that occasion, the deliberations of the legislature itself.

These are clearly hurtful acts; they may be very accurately defined; and penalties, of moderate severity, would be sufficient to deter from the performance of them. Satisfaction by the party offending to the party injured, would often, in offences of this description, be out of the question; because there would be no definite party to

whom an injury would be occasioned. It would only be necessary to ascertain the sorts of motives by which such offences would be liable to be produced, and to apply skilfully, as in other cases, motives of an opposite tendency, sufficient to counteract them. This would not be more difficult in this than in other cases, and it is not, therefore, necessary to explain at any length the mode of performing it.

One principle is to be carefully and most religiously observed, that of not imposing an atom of punishment for the purposes of *vengeance*. This is a principle, the justness and importance of which are so completely recognised, that we might have expected to be relieved ere now from the necessity of recommending attention to it. The fact, however, is, that so long as there are abuses in governments, so long will the men, who have the means of profiting by those abuses, exert themselves to multiply the list of offences against government, and to apply to them punishments of the greatest severity.

Punishments for contempt of court; punishments to vindicate the honour of the court, of the government, of the magistracy; punishments for the support of dignity; punishments severe in proportion as the dignity of the party offended is supposed to be high, and so on, are punishments almost always applied for purposes of vengeance, or the protection of the instruments of abuse. They are punishments, therefore, which will be rigidly excluded from a code which wisely and steadily pursues the general good.

Of Exhortations to obstruct the Operations of Government in detail, there are two Sorts: 1. The Direct; 2. The Implied, or Constructive.

What the *sort of acts* are, to which the exhortations of the press ought not to be applied, has been so far ascertained. The next point is, to determine with accuracy what *sort of exhortation* it is that ought to be forbidden.

To all those who profit by the abuses of government, that is, more especially, to all those who, in a defective government, wield any of its powers, it is of great importance to leave as undefined as possible the sort of exhortation that ought to be forbidden. The point of greatest importance to them is, to keep the people at large from complaining, or from knowing or thinking that they have any ground of complaint. If this object is fully attained, they may then, without anxiety, and without trouble, riot in the pleasures of misrule: there is no limit to the degree in which the few may pursue their own advantage at the expense of the many.

There can be nothing, therefore, in which they have a greater interest, than preventing the press from being employed in any such way as will lead the people to think that they have any thing, on the part of their rulers, of which to complain. All artifices possible will be sure to be employed to effect that prevention. And if it is enacted, that exhortations to acts which obstruct the operations of government in detail should be punished, *without defining accurately what sort of exhortations*, they will easily find expedients; which will, to a great extent, accomplish their purpose.

Under the sort of constructions which it will be their interest to apply, every thing which can be done by the press to make the people know or believe that there is any thing in the system of their government, or the conduct of their rulers, of which they have to complain, may be treated as an exhortation to obstruct the operations of government. Of these constructions our experience affords innumerable examples. Does not the imputing of defects to the government, or misconduct to those who wield the powers of government, tend to bring both "into

Liberty of
the Press.

Liberty of
the Press.

hatred and contempt?" And if the people hate and condemn the institutions and rulers of their country, will they not oppose their operations? The imputing of these faults, therefore, is it not, in essence and effect, an exhortation to oppose the operations of government? And are we to be governed, in our legislature, by the mere forms in which a set of words may appear, and not by our knowledge of their nature and consequences?

This is not only exceedingly plausible, but almost all the propositions which it involves are true. It is thus, therefore, the more easy to establish such a mode of interpreting an indefinite law of the press, as will prevent, or, where the people cannot yet bear a total prevention, will go far towards preventing, whatever can lead the people to believe that any thing is amiss in the manner in which they are ruled.

There are two species of exhortations, the one explicit and direct, the other implied and constructive. In the one, a particular act is pointed out, and the party or parties addressed are called upon to perform it. In the other, certain grounds are only laid, from which the opinion of the addresser, that the act ought to be performed, may, with more or less certainty, be inferred.

With respect to the first, there is no occasion for doubt. A direct and explicit exhortation to commit one of those acts, described above as obstructing the operations of government in detail, should be treated as an offence. The precise question is, whether any exhortation, which is only implied and constructive, should be considered an offence? In the answer to this question, almost every thing which relates to the use of the press in matters of government will be found to be involved.

Exhortations which are Implied and Constructive, ought not to be punished.

We have already divided the subject of resistance to government into two parts; first, that general resistance, the object of which is some great change in the government at large; and, secondly, resistance to this or that of its operations in detail.

We have already adduced an argument, which appears to us to be conclusive, to show that no exhortation, whether explicit or implied, direct or indirect, the object or tendency of which is to produce the first species of resistance, ought to be subject to legal restraint.

It is necessary here to enter a little more fully into the grounds of that opinion.

We think it will appear, with sufficient evidence, that, in the way of indirect exhortation to resistance, that is, in laying the grounds of dissatisfaction with the government, there is no medium between allowing every thing and allowing nothing; that the end, in short, which is sought to be gained, by allowing any thing to be published in censure of the government, cannot be obtained, without leaving it perfectly free to publish every thing.

The end which is sought to be obtained by allowing any thing to be said in censure of the government, is, to censure the goodness of the government; the most important of all the objects to the attainment of which the wisdom of man can be applied. If the goodness of government could be insured by any preferable means, it is evident that all censure of the government ought to be prohibited. All discontent with the government is only good, in so far as it is a means of removing real cause of discontent. If there is no cause, or if there is better means of removing the cause, the discontent is, of course, an evil, and that which produces it an evil.

So true it is, however, that the discontent of the people is the only means of removing the defects of vicious governments, that the freedom of the press, the main instru-

ment of creating discontent, is, in all civilized countries, Liberty of among all but the advocates of misgovernment, regarded the Press. as an indispensable security, and the greatest safeguard of the interests of mankind.

For what is meant by a vicious government? or where-in do the defects of government consist? Most assuredly they all consist in sacrificing the interests of the many to the interests of the few. The small number, in whose hands the powers of government are, in part directly, in part indirectly, placed, cannot fail, like other men, to have a greater regard for what is advantageous to themselves, than what is advantageous to other men. They pursue, therefore, their own advantage, in preference to that of the rest of the community. That is enough. Where there is nothing to check that propensity, all the evils of misgovernment, that is, in one word, the very worst evils by which human nature is afflicted, are the inevitable consequence.

There can be no adequate check without the freedom of the press. The evidence of this is irresistible. In all countries, the people either have a power legally and peaceably of removing their governors, or they have not that power. If they have not that power, they can only obtain any considerable ameliorations of their governments by resistance, by applying physical force to their rulers, or, at least, by threats so likely to be followed by performance, as may frighten their rulers into compliance. But resistance, to have this effect, must be general. To be general, it must spring from a general conformity of opinion, and a general knowledge of that conformity. How is this effect to be produced, but by some means, fully enjoyed by the people, of communicating their sentiments to one another? Unless where the people can all meet in general assembly, there is no other means of attaining this object, to be compared with the freedom of the press.

It is, no doubt, true, that in countries where the liberty of the press is unknown, bad governments are frequently overthrown. This is almost always accomplished by the military force, revenging some grievance of their own, or falling in with some heat and animosity of the people. But does it ever enable them to make a new government, in which any greater security is provided for their interests than there was before? In such cases, the people get rid of one set of rulers, whom they hate, only to obtain another set, with equal powers of doing them injury.

There are, however, we believe, some people who say, that though the liberty of the press is a necessary instrument to attain good government, yet, if it is fairly attained, and if legal and peaceable means are in the hands of the people of removing their governors for misconduct; if the people of England, for example, really chose the members of the House of Commons, and renewed their choice so frequently, as to have the power of removal after a short experience of misconduct; the freedom of the press would be unnecessary.

So far is this from being true, that it is doubtful whether a power in the people of choosing their own rulers, without the liberty of the press, would be an advantage.

Freedom of Censure on the Conduct of their Rulers, is necessary for the good of the People.

It is perfectly clear that all chance of advantage to the people, from having the choice of their rulers, depends upon their making a good choice. If they make a bad choice, if they elect people either incapable, or disinclined, to use well the power intrusted to them, they incur the same evils to which they are doomed when they are deprived of the due control over those by whom their affairs are administered.

Liberty of
the Press.

We may then ask, if there are any possible means by which the people can make a good choice, besides the *liberty of the press*? The very foundation of a good choice is knowledge. The fuller and more perfect the knowledge, the better the chance, where all sinister interest is absent, of a good choice. How can the people receive the most perfect knowledge relative to the characters of those who present themselves to their choice, but by information conveyed freely, and without reserve, from one to another?

There is another use of the freedom of the press, no less deserving the most profound attention, that of making known the conduct of the individuals who have been chosen. This latter service is of so much importance, that upon it the whole value of the former depends.

This is capable of being rigidly demonstrated. No benefit is obtained by making choice of a man who is well qualified to serve the people, and also well inclined to serve them, if you place him in a situation in which he will have preponderant motives to serve himself at their expense.

If any set of men are chosen to wield the powers of government, while the people have not the means of knowing in what manner they discharge their duties, they will have the means of serving themselves at the expense of the people; and all the miseries of evil government are the certain consequence.

Suppose the people to choose the members of the legislative assembly, with power of rechoosing or dismissing them at short intervals; to what desirable end could these powers be exercised, without the liberty of the press? Suppose that any one of those whom they have chosen has misconducted himself, or promoted, as far as depended upon him, the ends of misgovernment, how are the people to know that the powers with which they had intrusted him had been treacherously employed?

If they do not know, they will rechoose him, and that as cordially as the man who has served them with the greatest fidelity. This they are under a deplorable necessity of doing, even to be just; for, as they know no difference between him and the best, it would be on their part iniquity to make any. The consequences would be fatal. If one man saw that he might promote misrule for his own advantage, so would another; so of course would they all. In these circumstances we see laid the foundation on which, in every country, bad government is reared. On this foundation it is impossible that it should not be reared. When the causes are the same, who can expect that the effects will be different? It is unnecessary to dwell upon these fundamental truths, because they underlie every consideration of the theory of government.

Without the knowledge, then, of what is done by their representatives, in the use of the powers intrusted to them, the people cannot profit by the power of choosing them, and the advantages of good government are unattainable. It will not surely cost many words to satisfy all classes of readers, that, without the free and unrestrained use of the press, the requisite knowledge cannot be obtained.

That an accurate report of what is done by each of the representatives, a transcript of his speeches, and a statement of his propositions and votes, is necessary to be laid before the people, to enable them to judge of his conduct, nobody, we presume, will deny. This requires the use of the cheapest means of communication, and, we add, the free use of those means. Unless every man has the liberty of publishing the proceedings of the legislative assembly, the people can have no security that they are fairly published. If it is in the power of their rulers to permit one person, and forbid another, the people may be sure that a false report, that is, a report calculated to

make them believe that they are well governed when they are ill governed, will be often presented to them.

Liberty of
the Press.

One thing more is necessary, and so necessary, that if it is wanting, the other might as well be wanting also. The publication of the proceedings tells what is done. This, however, is useless, unless a correct judgment is passed upon what is done.

We have brought this inquiry, then, to an important point. From the very theory of government we may see that, unless the people held in their own hands an effectual power of control on the acts of their government, the government will be inevitably vicious. We have now seen that they cannot exercise this control to any beneficial purpose, without the means of forming a correct judgment upon the conduct of their representatives. We have likewise seen, that one of the means necessary to enable them to judge correctly of the conduct of their representatives, is the liberty to every body of publishing reports of what they do. It remains to inquire by what other acts the press can be made to contribute to the same desirable end.

What is wanted is, that all the people, or as many of them as possible, should estimate correctly the consequences of the acts proposed or done by their representatives, and also that they should know what acts might have been proposed, if the best were not proposed, from which better consequences would have followed. This end would be accomplished most effectually, if those who are sufficiently enlightened would point out to those who are in danger of mistakes, the true conclusions; and, showing the weight of evidence to be in their favour, should obtain for them the universal assent.

How is this to be accomplished? In what manner are those wise men to be chosen? And who are to be the choosers? Directly the object cannot be attained. There are no distinct and indubitable marks by which wisdom, and less by which integrity, is to be known. And who is to be trusted with the privilege of pointing them out? They whose judgment requires to be directed are not well qualified to determine who shall direct them. And if the rulers are to choose, they will employ none but those who will act in conformity to their views, and enable them to benefit themselves by the pillage and oppression of the people.

As there is no possible organ of choice, no choice whatever ought to be made. If no choice is to be made, every man that pleases ought to be allowed. All this is indubitable. The consequences of denying any part of it are so obvious, that hardly any man, we suppose, will risk the imputations to which such a denial would justly expose him.

They who say that no choice ought to be made, say, in effect, that no limit whatsoever ought to be imposed upon the liberty of the press. The one of these propositions is involved in the other. To impose any restraint upon the liberty of the press, is undoubtedly to make a choice. If the restraint is imposed by the government, it is the government that chooses the directors of the public mind. If any government chooses the directors of the public mind, that government is despotic.

Suppose that, by the restraint imposed upon the liberty of the press, all censure of the government is forbidden; here is undoubtedly a choice. The government, in this case, virtually says, the people who might attempt the task of directing the public mind are of two sorts; one, those who would censure; another, those who would not censure; I choose the latter.

Suppose that not every censure, but only such and such kinds of censure, are forbidden; here, again, is still a choice, while confessedly there is no party to whom the power of choosing for the rest can with safety be given.

If not every censure, but only some censures, are to be

Liberty of the Press. forbidden, what are those to which the prohibition should extend? The answer to this question will elucidate nearly all that yet remains in any degree obscure of the doctrine of the liberty of the press.

It will not be said that any censure which is just should be forbidden; because that would undoubtedly be to detract from the means of enabling the people to form correct judgments; and we have, we trust, rendered it indisputable that no source of benefit to society is at all to be compared with that of correct judgments, on their government and its functionaries, formed by the people, and determining their actions.

But what censures are just and what are unjust; in other words, what are the conclusions which ought to be formed respecting the properties and the acts of the government, is exactly the point to be determined. If you say that no man is to pass an unjust censure upon the government, who is to judge? It is surely unnecessary to repeat the proof of the proposition, that there is nobody who can safely be permitted to judge. The path of practical wisdom is as clear as day: all censures must be permitted equally, just and unjust.

Where various conclusions are formed among a number of men, upon a subject on which it would be unsafe, and therefore improper, to give any minor portion of them a power of determining for the rest, only one expedient remains. Fortunately, that is an expedient, the operation of which is powerful, and its effects beneficial in the highest degree. All the conclusions which have formed themselves in the minds of different individuals should be openly adduced, and the power of comparison and choice should be granted to all. Where there is no motive to attach a man to error, it is natural to him to embrace the truth; especially if pains are taken to adapt the explanation to his capacity. Every man possessed of reason is accustomed to weigh evidence, and to be guided and determined by its preponderance. When various conclusions are, with their evidence, presented with equal care and with equal skill, there is a moral certainty, though some few may be misguided, that the greater number will judge right, and that the greatest force of evidence, wherever it is, will produce the greatest impression.

As this is a proposition upon which everything depends, it is happy that the evidence of it should be so very clear and striking. There is, indeed, hardly any law of human nature more generally recognised, wherever there is not a motive to deny its existence. "To the position of Tully, that if Virtue could be seen, she must be loved, may be added," says Dr Johnson, "that if Truth could be heard, she must be obeyed." (*Rambler*, No. 87.) "Je vous plains, mes Pères," says M. Pascal to the Jesuits "d'avoir recours à de tels remèdes. Vous croyez avoir la force et l'impunité: mais je crois avoir la vérité, et l'innocence. C'est une étrange et longue guerre que celle où la violence essaie d'opprimer la vérité. Tous les efforts de la violence ne peuvent affaiblir la vérité, et ne servent qu'à la relever d'avantage: toutes les lumières de la vérité ne peuvent rien pour arrêter la violence, et ne font que l'irriter encore plus. Quand la force combat la force, la plus puissante détruit la moindre: quand l'on expose les discours aux discours, ceux qui sont véritables et convainquants confondent et dissipent ceux qui n'ont que la vanité et le mensonge." (*Lettres Provinciales*, 12.)—"Reason," says Burke, "clearly and manfully delivered, has in itself a mighty force; but reason, in the mouth of legal authority, is, I may fairly say, irresistible." (*Letter on a Regicide Peace*.)

It is of importance to show how many of the greatest men, of all ages and countries, have borne testimony to the prevalence of true over false conclusions, when both

are fairly offered to the human mind. "Truth," says Mr Locke, "certainly would do well enough, if she were once left to shift for herself. She seldom has received, and I fear never will receive, much assistance from the power of great men, to whom she is but rarely known, and more rarely welcome. She is not taught by laws, nor has she any need of force to procure her entrance into the minds of men." (*Letter on Toleration*.) The following is the emphatical language of Montesquieu:—"La raison a un empire naturel; elle a même un empire tyrannique: on lui résiste, mais cette résistance est son triomphe, encore un peu de temps, et l'on sera forcé de revenir à elle." (*Esprit de Loix*, l. xxviii., ch. 38.) "It is noted out of Cicero, by Machiavel, that the people, though they are not so prone to find out truth of themselves, as to follow custom, or run into error, yet if they be shown truth, they not only acknowledge and embrace it very suddenly, but are the most constant and faithful guardians and conservators of it." (*Harrington*.) "The labour of a confutation," says Chillingworth, "I have not in any place found such labour or difficulty, but that it was undertakeable by a man of very mean abilities; and the reason is, because it is Truth I plead for; which is so strong an argument for itself, that it needs only light to discover it." (*Religion of Protestants*.) About things on which the public thinks long," says Dr Johnson, "it commonly attains to think right." (*Life of Addison*.) "The adversary," says Dr Campbell, "is both subtle and powerful. With such an adversary, I should on very unequal terms enter the lists, had I not the advantage of being on the side of truth. And an eminent advantage this doubtless is. It requires but moderate abilities to speak in defence of a good cause. A good cause demands but a distinct exposition, and a fair hearing; and we may say, with great propriety, it will speak for itself." (*Campbell on Miracles*, Introd.)

We have, then, arrived at the following important conclusions, viz.,—That there is no safety to the people in allowing anybody to choose opinions for them; that there are no marks by which it can be decided beforehand what opinions are true and what are false; that there must, therefore, be equal freedom of declaring all opinions, both true and false; and that, when all opinions, true and false, are equally declared, the assent of the greater number, when their interests are not opposed to them, may always be expected to be given to the true. These principles, the foundation of which appears to be impregnable, suffice for the speedy determination of every practical question.

All censure thrown upon the government, all censure thrown either upon the institutions of the government, or upon the conduct of any of the functionaries of government, supreme or subordinate, has a tendency to produce resistance to the government.

Of the censures thrown upon government, some may have a tendency to produce resistance to the operations of government in detail; others that general resistance which has in view some great alteration in the government.

Of the first sort would be any such accusation of the conduct and disposition of a judge as might excite the people, whose sympathies were roused in favour of the individual against whom his sentence was to operate, to rescue him from the officers of justice. We have already shown that such a rescue ought to be punished, and any direct exhortation to it ought to be punished. It will now be evident, we trust, that no censure on the judge, though capable of being treated as an indirect exhortation, ought to be punished.

The reason is conclusive. The people ought to know, if possible, the real qualities of the actions of those who are intrusted with any share in the management of their affairs. This they have no chance of knowing, without the

Liberty of
the Press.

Liberty of unlimited power of censure upon those actions, both in gross and detail. To see the full force of these propositions, it is only necessary to apply the principles which have been already established.

If the people have not the means of knowing the actions of all public functionaries, they have no security for the good conduct even of their representatives. Suppose it is the duty of their representatives to watch the conduct of the judges, and secure the perfection of judicature, the people cannot know whether their representatives perform this duty, unless they know what the conduct of the judges is. Ignorance of this would of itself suffice to vitiate the government. A door would be left open, through which the rulers might benefit themselves at the expense of the people. All the profit to be made by an abuse of the power of justice, would thus become the profit of the representatives, by whom it would be allowed and encouraged, as far as the knowledge which they could not withhold from the people would permit.

That the people ought, therefore, to know the conduct of their judges, and when we say judges we mean every other functionary, and the more perfectly the better, may be laid down as indubitable. They are deprived of all trust-worthy means of knowing, if any limit whatsoever is placed to the power of censure.

All censure consists in the delivery of an unfavourable opinion, with or without the grounds of it. This is the essence of censure. But if the conduct of the judge deserves that an unfavourable opinion should be entertained of it, the more perfectly that is known to the people the better.

The conduct of the judge, on this occasion, says a defender, does not deserve an unfavourable opinion. A public expression of such an opinion ought, therefore, to be prohibited. But there are occasions on which the conduct of judges deserves an unfavourable opinion. When it is deserved, there is no security for good government, unless it is allowed to be made known. How can you allow an unfavourable opinion to be delivered in the one case, and not delivered in the other? To have the benefit of it in the one case, you must submit to the evil of it in the other.

In matters of Government, undeserved Praise is as mischievous as undeserved Blame.

As the real point of importance is, to establish correct opinions in the minds of the people, it is as mischievous to inculcate a favourable opinion when an unfavourable is deserved, as an unfavourable when a favourable is deserved; and, in the eye of reason, it is incontrovertible, that, if the one deserves to be prevented by punishment, so does the other.

But if an unfavourable opinion is pronounced of any public functionary—of a judge, for example—would you have it left uncontradicted? Would you not grant the liberty of calling in question the truth of the allegations, and of supporting a different opinion? If not, the character of no public functionary would be safe, and any man, however deserving, might be made to appear the proper object of the most unfavourable sentiments. Why should not the two cases be treated equally? Why should not the favourable, as well as the unfavourable opinion, be open to contradiction.

It is perfectly certain, that it is not in the power of law to mark out, by antecedent definition, any sort of men, of whom it can say, all opinions favourable to such men shall be punished. It can never be affirmed of any men beforehand, that they will certainly perform such and such injurious actions. If they do not perform them, all declarations conformable with the matter of fact are good. But

the question is, whether they have performed them? One Liberty of man affirms that they have. Is that to be taken for granted? the Press. And is no man to be allowed to affirm the contrary, and to suit the grounds upon which the allegations of the other man are supported? It is by weighing well the evidence on both sides that a well-rounded opinion is capable of being formed. And it is certain, that the best security for having the evidence on both sides fully adduced, and the strength and weakness of it perfectly disclosed, is by permitting all those who are attached to different opinions to do what they can for the support of them.

If it is evident that it ought not to be permitted to speak evil of public functionaries without limit, while any limit is put to the power of speaking well of them; it is equally evident that, for the purpose of forming a correct opinion of their conduct, it ought not to be permitted to speak well of them, and oppose any limit whatsoever to the power of speaking ill of them.

It ought not to be permitted to speak evil of them without an equal liberty of speaking well; because, in that case, the evidence against them might be made to appear much stronger than it was. It ought not to be permitted to speak well of them without an equal liberty of speaking ill; because, in that case, the evidence in favour of them might be made to appear much greater than it really was. In either case, the people would be misguided, and defrauded of that moral knowledge of the conduct of their rulers, the paramount importance of which has so fully appeared.

It may be said (as by the short-sighted, if we did not anticipate them, it would be said), that if, by limiting the power of censure, the people are made to judge more favourably of their rulers than they deserve, the evil is small; but if they are permitted to form a very unfavourable opinion, the consequences are alarming.

We believe it may be rigidly demonstrated, that no evils are greater than those which result from a more favourable opinion of their rulers, on the part of the people, than their rulers deserve; because just as far as that undue favour extends, bad government is secured. By an opinion of their rulers more favourable than they deserve, is implied an ignorance on the part of the people of certain acts of their rulers by which the people suffer. All acts by which the rulers have any motive to make the people suffer, are acts by which the rulers profit. When the ignorance of the people extends to material points, all the evils of bad government are secured. These are the greatest of all possible evils. To this it will not be said that the ignorance of the people ought to extend. On all material points, it is admitted, then, that the freedom of censure ought to be complete. But if it is to be allowed on great points, on those where it is calculated to excite the greatest disapprobation; what can be thought of their consistency, who would restrain it on those where it is only calculated to excite a small? If it is proper to protect the people from great injuries at the hands of their rulers, by exciting a strong, it is good to protect them against small injuries, by exciting a weak disapprobation.

To public functionaries may be imputed either acts which they have not performed, or a want of certain qualifications, moral or intellectual, which they ought to possess.

With respect to acts, and even dispositions, which do not, either directly or indirectly, concern their public function, the same protection may be safely extended to them as to private men.

Acts, in their public capacity, which they have not performed, may be imputed to them either by mere forgery, and without any appearance of ground, or they may be imputed with some appearance of ground. From permitting the former, no good can be derived. They ought, there-

Liberty of the Press. injurious to individuals in their private capacity. That there should be no restraint in imputing actions to any public functionary which he may appear to have done, flows immediately from the principles already established, and requires not that any thing should here be added to its proof. Any appearance sufficient to lay the foundation of the slightest suspicion, renders it useful to call the attention of the public to the suspected part, which can only be done by making the suspicion known. A man may, indeed, publish, as a matter of fact, what is supported by appearances which would only justify the slightest suspicion. In that case, he is sure of incurring the disgrace of temerity, if not of malignity; and this is all the penalty which needs or can safely be inflicted upon him.

In imputing inaptitude to a public functionary, on the score either of intellectual or moral qualities, scarcely any limitation would be safe. Every man ought to have liberty to declare upon this subject any opinion which he pleases, and support it by any evidence which he may think adapted to the end. If, in supporting his opinion of the inaptitude of any public functionary, he imputes to him actions which there is not even an appearance of his having performed, that limited prohibition, the propriety of which we have just recognised, will strictly apply. With this exception, freedom should be unimpaired.

We have now, therefore, explained, we hope sufficiently, in what manner the principles which we have established require that the use of the press should be regulated in speaking of the actions of public functionaries, and of their fitness for the duties which they are appointed to discharge, whether those functionaries are the immediate representatives of the people, or others whom it is the business of those representatives to control.

Freedom of Censure on the Institutions of Government is necessary for the good of the People.

We have next to inquire in what manner those principles require that the use of the press should be regulated in speaking of the *institutions* of government. The illustrations already adduced will supersede the use of many words upon this part of the subject.

Institutions of government are good in proportion as they save the people from evil. Institutions of government are bad in proportion as they are the cause of evil to the people, either by what they create, or what they fail in preventing.

According to this statement, which it is impossible to controvert, institutions of government may, in strict propriety of speech, be said to be the cause of all the evil which they do not save the people from, and from which the people would be saved by any other institutions.

It is therefore of the highest importance that the people should know what are the institutions which save from the greatest quantity of evil, and how much their own institutions want of being those best institutions.

Institutions of government are bad, either because those in whose hands the powers of government are placed, do not know that they are bad, and, though willing, cannot improve them; or they are bad, because those who have in their hands the powers of government do not wish that they should be improved.

When the rulers are willing, but do not know how to improve the institutions of government, every thing which leads to a knowledge of their defects is desirable to both rulers and people. That which most certainly leads to such knowledge is, that every man who thinks he understands any thing of the subject, should produce his opinions, with the evidence on which they are supported, and that every man who disapproves of these opinions should state his ob-

jections. All the knowledge which all the individuals in the society possess upon the subject is thus brought, as it were, to a common stock or treasury; while every thing which has the appearance of being knowledge, but is only a counterfeit of knowledge, is assayed and rejected. Every subject has the benefit of becoming thoroughly understood, when, by the delivery of all opinions, it is presented in all points of view; when all the evidence upon both sides is brought forward, and all those who are most interested in showing the weakness of what is weak in it, and the strength of what is strong, are, by the freedom of the press, permitted, and by the warmth of discussion excited, to devote to it the keenest application of their faculties. False opinions will then be delivered. True; but when are we most secure against the influence of false opinions? Most assuredly when the grounds of those opinions are the most thoroughly searched. When are the grounds of opinions most thoroughly searched? When discussion upon the subject is the most general and the most intense; when the greatest number of qualified persons engage in the discussion, and are excited by all the warmth of competition, and all the interest of important consequences, to study the subject with the deepest attention. To give a body of rulers, or any other body of men, a power of choosing, for the rest, opinions upon government, without discussion, we have already seen, upon good evidence, is the way to secure the prevalence of the most destructive errors.

When institutions are bad, and the rulers would gladly change them if they knew they were bad, discussion, it will not be disputed, would be good for both parties, rulers and ruled. There is, however, another case, and that by far the most common, where the rulers are attached to the bad institutions, and are disposed to do all in their power to prevent any alteration. This is the case with all institutions which leave it in the power of the men who are intrusted with the powers of government, to make use of them for their own advantage, to the detriment of the people; in other words, which enable them to do injury to the people, or prevent the people from good. This is the case with by far the greater number of those institutions by which the people suffer. They are institutions contrived for benefiting the few at the cost of the many.

With respect, therefore, to the greater number of defective institutions, it is the interest of the rulers that true opinions should not prevail. But with respect to those institutions, it is of still greater importance to the people that discussion should be free. Such institutions as the rulers would improve, if they knew that they were defective, will be improved as the rulers themselves become sensible of their defects. Such defective institutions as the rulers would not wish to see improved, will never be improved, unless the knowledge of those defects is diffused among the people, and excites among them a disapprobation which the rulers do not think it prudent to disregard.

That the prevalence of true opinions among the people, relative to those defects in their political institutions, by which the rulers profit at their expense, is of the utmost importance to the people, is therefore a proposition which no improbity will dare openly to controvert. That freedom of discussion is the only security which the people can have for the prevalence of true opinions, has already been proved. It is therefore proved, that freedom of discussion, in its utmost perfection, they ought to enjoy.

What is included in the term, *freedom of discussion*, is evident from what has already been said.

Freedom of discussion means the power of presenting all opinions equally, relative to the subject of discussion; and of recommending them by any medium of persuasion which the author may think proper to employ. If any obstruction is given to the delivering of one sort of opinions,

Liberty of the Press. not given to the delivering of another; if any advantage is attached to the delivering of one sort of opinions, not attached to the delivery of another; so far equality of treatment is destroyed, and so far the freedom of discussion is infringed; so far truth is not left to the support of her own evidence; and so far, if the advantages are attached to the side of error, truth is deprived of her chance of prevailing.

To attach advantage to the delivering of one set of opinions, disadvantage to the delivering of another, is to make a choice. But we have already seen, that it is not safe for the people to let any body choose opinions for them. If it be said, that the people themselves might be the authors of this preference, what is this but to say, that the people can choose better before discussion than after; before they have obtained information than after it? No; if the people choose before discussion, before information, they cannot choose for themselves. They must follow blindly the impulse of certain individuals, who, therefore, choose for them. This is, therefore, a pretence, for the purpose of disguising the truth, and cheating the people of that choice, upon which all their security for good government depends.

If these deductions are as clear and incontrovertible as to us they appear to be, the inquiry respecting the principles which ought to regulate the use of the press is drawn pretty nearly to its close. We have shown that, as far as regards the violation of the rights of individuals, in respect to both persons and things, no definition on account of the press is required. We have shown in what manner the rights of individuals, in regard to reputation, should be defined by the civil code, and the violation of them prevented by the penal. We next proceeded to what may be considered as the main branch of the inquiry, namely, the use of the press in speaking of the institutions and functionaries of government. We have found that, in this respect, the freedom of the press is of such importance, that there is no security for good government without it. We have also found, that the use of it, in respect to those subjects, admits of but two useful restrictions, that of a direct exhortation to obstruct any of the operations of government in detail, and that of imputing to a functionary of government a criminal act, which there was no ground, nor even an appearance of ground, to impute to him. These restrictions, of course, it would be very easy to define in the criminal code, and to find appropriate motives to sanction. In all other respects, we have seen that the press ought to be free; that if there is any limit to the power of delivering unfavourable opinions respecting either the functionaries or the institutions of government, and of recommending those opinions by any media, with the single exception of false facts, under the circumstances mentioned above, the benefits which may be derived from the freedom of the press are so greatly infringed, that hardly any security for good government can remain.

IV.—LIMITATIONS TO FREEDOM OF DISCUSSION, WHICH INVOLVE ITS DESTRUCTION.

In the administration of English law, or rather of what is called law, upon this subject, without being any thing better than the arbitrary will of the judges, it is said, that though discussion should be free, it should be "decent;" and that all "indecent" in discussion should be punished as a libel. It is not our object in this discourse to give an exposition of the manifold deformities of the English law of libel. If we have been successful in developing the true principles which ought to regulate the freedom of the press, every reader may, by an application of those principles, determine what he ought to think of the several particulars which there may attract his attention. We shall

Liberty of the Press. confine ourselves to a short notice of those *dicta*, or doctrines, which seem most likely to be pleaded, in opposition to the principles which we have endeavoured to establish.

The question is, whether *indecent* discussion should be prohibited? To answer this question, we must, of course, inquire, what is meant by indecent.

In English libel law, where this term holds so distinguished a place, is it not defined?

English legislators have not hitherto been good at defining; and English lawyers have always vehemently condemned, and grossly abused it. The word "indecent," therefore, has always been a term under which it was not difficult, on each occasion, for the judge to include whatever he did not like. "Decent," and "what the judge likes," have been pretty nearly synonymous.

Indecency of discussion cannot mean the delivery either of true or of false opinions, because discussion implies both. In all discussion there is supposed at least two parties, one who affirms, and one who denies. One of them must be in the wrong.

The delivery, though not of all true opinions, yet of some, may be said to be indecent. All opinions are either favourable or unfavourable. True opinions that are favourable to government and its functionaries will not be said to be indecent; nor will all opinions that are true and unfavourable be marked out for prohibition under that name. Opinions unfavourable may either be greatly unfavourable or slightly unfavourable. If any unfavourable opinions are exempted from the charge of indecency, it must be those which are slightly so. But observe what would be the consequence of prohibiting, as indecent, those which are greatly unfavourable. A true opinion, greatly unfavourable to a functionary, or institution, of government, is an opinion that the functionary, or institution, is greatly hurtful to the people. You would permit the slight evil to be spoken of, and hence removed; you would not permit the great evil to be spoken of.

If no *true* opinion can be regarded as indecent, meaning by indecent, requiring *punishment*, we must inquire if any *false* opinion on matters of government ought to be treated as such. If all false opinions are indecent, all discussion is indecent. All false opinions, therefore, are not indecent. The English libel law does not treat any favourable opinions, how much soever false, as indecent. If all opinions that are false and unfavourable are said to be indecent, who is to judge if they are false? It has been already proved, that the people can confide the power of determining what opinions are true, what are false, to none but themselves. Nothing can resist the following argument. Either the people do know, or they do not know, that an opinion is false: if they do not know, they can permit nobody to judge for them, and must leave discussion its free course: if they do know, all infliction of evil for the delivery of an opinion which then can do no harm, would be purely mischievous and utterly absurd.

If all opinions, true and false, must be allowed to be delivered, so must all the media of proof. We need not examine minutely the truth of this inference, because it will probably be allowed. It will be said, however, that though all opinions may be delivered, and the grounds of them stated, it must be done in calm and gentle language. Vehement expressions, all words and phrases calculated to inflame, may justly be regarded as indecent, because they have a tendency rather to pervert than rectify the judgment.

To examine this proposition, it must be taken out of that state of vagueness in which so many things are left by the English law, and made, if possible, to speak a language, the meaning of which may be ascertained.

We have just decided, and, as it appeared, on very substantial grounds, that the statement of no opinion, favour-

Liberty of the Press. able or unfavourable, true or false, with its media of proof, ought to be forbidden. No language necessary for that purpose can be indecent, meaning here, as before, nothing by that term, as nothing can be meant, but simply *punishable*, or proper for punishment.

But the only difference between delivering an opinion one way and another way is, that in the one case it is simply delivered, in the other it is delivered with indications of passion. The meaning of the phrase in question then must be, that an opinion must not be delivered with indications of passion.

What! not even a favourable one?

"Oh, yes; a favourable one. Merited *praise* ought to be delivered with warmth."

Here, then, is inequality, and therefore mischief, at once. An opinion, meaning here a true opinion, if it is favourable, you allow, if unfavourable, you do not allow, to be delivered in a certain way. Why? Because in that way, you say, it is calculated to make an undue impression. Opinions favourable, then, you wish to make an undue impression, and by that confess the wickedness of your intention. You desire that the people should think better of the institutions and functionaries of their government than they deserve; in other words, you wish the government to be bad.

If opinions, to what degree soever unfavourable, may be freely and fully delivered, there are two conclusive reasons why the terms in which they are delivered should not be liable to punishment. In the first place, the difference between one mode of delivery and another is of little consequence. In the second place, you cannot forbid the delivery in one set of terms, without giving a power of preventing it in almost all.

First, the difference is of little consequence. If I say barely that such a functionary of government, or such an institution of government, is the cause of great injury and suffering to the people, all that I can do more by any language is, to give intimation, that the conduct of such functionary, or the existence of such institution, excites in me great contempt, or great anger, or great hatred, and ought to excite them in others. But if I put this in the way of a direct proposition, I may do so, because then it will be a naked statement with regard to a matter of fact, and cannot be forbidden, without overthrowing the whole of the doctrine which we have already established.

If, then, I give indication of certain sentiments of mine, and of my opinion of what ought to be the sentiments of others *explicitly*, I ought, you say, to be held innocent; if *implicitly*, guilty. Implicitly, or explicitly, that is the difference, and the whole of the difference. If I say, that such a judge, on such an occasion, took a bribe, and pronounced an unjust decision, which ruined a meritorious man and his family, this is a simple declaration of opinion, and ought not, according to the doctrine already established, to meet with the smallest obstruction. If I also state the matter of fact with regard to myself, that this action has excited in me great compassion for the injured family, and great anger and hatred against the author of their wrongs, this must be fully allowed. I must further be allowed to express freely my opinion, that this action ought to excite similar sentiments in other members of the community, and that the judge ought to receive an appropriate punishment. Much of all this, however, I may say in another manner. I may say it much more shortly by implication. Here, I may cry, is an act for the indignation of mankind. Here is a villain, who, invested with the most sacred of trusts, has prostituted it to the vilest of purposes. Why is he not an object of public execration? Why are not the vials of wrath already poured forth upon his odious head? All this means nothing, but that he has committed the act; that I hate him for it,

and commiserate the sufferers; that I think he ought to be punished; and that other people ought to feel as I do. It cannot be pretended, that between these two modes of expression, the difference, in point of real and ultimate effect, can be considerable. For a momentary warmth, the passionate language may have considerable power. The permanent opinion formed of the character of the man, as well as the punishment, which, under a tolerable administration of law, he can sustain, must depend wholly upon the real state of the facts; any peculiarity in the language in which the facts may have been originally announced soon loses its effect. If that language has expressed no more indignation than what was really due, it has done nothing more than what the knowledge of the facts themselves would have done. If it has expressed more indignation than what was due, the knowledge of the facts operates immediately to extinguish it, and, what is more, to excite an unfavourable opinion of him who had thus displayed his intemperance. No evil then is produced, or none but what is very slight and momentary. If there should be a short-lived excess of unfavourable feeling, we have next to consider what is the proper remedy. Punishment should never be applied where the end can be obtained by more desirable means. To desire any excess of unfavourable feeling, all that is necessary is to show the precise state of the facts, and the real amount of the evil which they import. All excess of feeling arises from imputing to the facts a greater efficacy in the way of evil than belongs to them. Correct this opinion, and the remedy is complete.

Secondly, you cannot forbid the use of passionate language, without giving a power of obstructing the use of censorial language altogether. The reason exists in the very nature of language. You cannot speak of moral acts in language which does not imply approbation and disapprobation. All such language may be termed *passionate language*. How can you point out a line where passionate language begins, dispassionate ends? The effect of words upon the mind depends upon the associations which we have with them. But no two men have the same associations with the same words. A word which may excite strains of emotion in one breast, will excite none in another. A word may appear to one man a passionate word, which does not appear so to another. Suppose the legislature were to say, that all censure, conveyed in *passionate language*, shall be punished, hardly could the vices of either the functionaries or the institutions of government be spoken of in any language which the judges might not condemn as *passionate language*, and which they would not have an interest, in league with other functionaries, to prohibit by their condemnation. The evil, therefore, which must of necessity be incurred by a power to punish language to which the name of *passionate* could be applied, would be immense. The evil which is incurred by leaving it exempt from punishment is too insignificant to allow that almost any thing should be risked for preventing it.

Religion, in some of its shapes, has, in most countries, been placed on the footing of an institution of the state. Ought the freedom of the press to be as complete, in regard to this, as we have seen that it ought to be, in regard to all other institutions of the state? If any one says that it ought not, it is incumbent upon him to show where, in the principles, which are applicable to the other institutions, fail in their application to this.

We have seen, that, in regard to all other institutions, it is unsafe for the people to permit any but themselves to choose opinions for them. Nothing can be more certain, than that it is unsafe for them to permit any but themselves to choose for them in religion.

If they part with the power of choosing their own reli-

Libourne gious opinions, they part with every power. It is well known with what ease religious opinions can be made to embrace everything upon which the unlimited power of rulers, and the utmost degradation of the people, depend. The doctrine of *passive obedience* and non-resistance was a *religious doctrine*. Permit any man, or any set of men, to say what shall, and what shall not, be religious opinions, you make them despotic immediately.

This is so obvious, that it requires neither illustration nor proof.

But if the people here, too, must choose opinions for themselves, discussion must have its course; the same propositions which we have proved to be true in regard to other institutions are true in regard to this; and no opinion ought to be impeded more than another by anything but the adduction of evidence on the opposite side. (J. M.—L.)

LIBOURNE (the ancient *Liburnum*), a town of France, capital of a cognominal arrondissement in the department of Gironde, on the right bank of the Dordogne, at the influx of the Isle, and on the Tours and Bordeaux Railway, 22 miles E.N.E. of the latter town. A handsome brick bridge of nine arches crosses the Dordogne, while the Isle is crossed by an iron suspension-bridge. Its port is tidal, and capable of receiving vessels of 300 tons. This is one of the *Bastides*, or free towns, founded by Edward I. of England, and is

remarkable for its neat and regular appearance. It is surrounded by walls affording agreeable promenades, and has extensive cavalry barracks. It is the seat of thousands of primary instance and commerce; and has a communal college, theatre, and public library of 5000 vols. The manufactures comprise cotton and woollen stuffs, rope, nails, leather, &c. Ship-building is also carried on. Its chief trade is in corn, salt, wine, and brandy. Pop. (1851) 11,552.

LIBRA. See WEIGHTS AND MEASURES.

LIBRARIES.

LIBRARY, in ordinary language, may mean either (1.) a collection of books, public or private; (2.) A building or apartment destined for the reception and systematic arrangement of such a collection; or (3.) a series of treatises on a particular subject,—as, for example, *Library of Anglo-Catholic Theology*,—or a series of works on various subjects, published on some uniform plan, such as *Murray's Family Library*, and the like. It is in the two former senses only that the term is employed in this article.

roused to the importance of supplying this deficiency in an effective and thorough manner.

In the formation of a library of this description, it will be well, we think, for the promoters to fix, at the outset, upon some particular class or classes of literature, in which it shall be pre-eminently well provided. What these chosen subjects shall be, must, of course, depend in each case upon special circumstances, which will be different in different places. But be these circumstances what they may, some one important class, at least, should be selected, in which the library shall have, as early as possible, a systematic collection, not a mere chance aggregation of books. In the instances of the Town Libraries which have been recently established, the largest sum available for purchases has not (under very favourable conditions) exceeded L.6000. Twice that sum would be utterly insufficient for the formation of a really valuable library upon *all* subjects, even if it were restricted to books in English. But a much smaller sum than L.6000, if appropriated on the principle of spending most of it in the purchase of books on some one leading subject,—say, for example, on British history,—and the remainder on the best and most indispensable books, only, on other subjects of general interest, will lay the foundation of a library, which, from the beginning, will tend as well to make students as to help them.

Another point which should receive careful attention, in the establishment of a library of this class, is the collection of works illustrative of the local history of the town and county in which it is placed. Many generations have elapsed since John Bale expressed² his earnest wish that in every shire of England there were "at least one library for the preservation of noble works and preferment of good learning." Had effect been given to that desire in his own day, many more of the choice treasures of the monastic libraries would have been saved from destruction, and much valuable material for local topography would have been accessible, which is now irrecoverably lost. In a Town Library, every thing of this kind which is procurable should be stored up for the future historian. Every book and every fugitive tract that bears on the history or antiquities, the fauna or flora, the trade or politics of the district; on the lives of local worthies, or on local affairs and institutions of whatever description, should be sought for and preserved. And whenever unprinted materials of this sort are known to exist in

(1.) OF THE COLLECTION OF BOOKS BY PURCHASE.

Collection
of books by
purchase.

In the formation of a Public Library, the first concern of the founders should obviously be to acquire a distinct conception of the aims with which it is established, and of the studies which it is intended principally to facilitate. To a great national library, indeed, all sorts and varieties of books are welcome; but a library of this kind is rather a growth than a formation. The chief libraries of a country ought, unquestionably, to be encyclopædical, because even the "trash" of one generation becomes the highly-prized treasure of another. What a Bodley, at the end of the sixteenth century, calls "riff-raff, . . . which a library-keeper should disdain to seek out to deliver to any man,"¹ a Bodley's librarian has to buy almost for its weight in gold at the beginning of the nineteenth century. For, by that time, it comes to be apparent that the most obscure pamphlet, or the flimsiest ballad, may throw a ray of light upon some pregnant fact of history, or may serve as the key to a mystery in some life-career which gave to an age its very "form and presure."

But, besides these great repositories, many libraries are needed of narrower aims and of more specific character. Of these, some are professional, such as—Law Libraries, Divinity Libraries, Medical Libraries, and the like. In collections of this kind, no country, perhaps, is richer than our own; and for the formation of new ones, wherever they may be needed, many and excellent appliances lie ready to the hand. Far more difficult will be the labour of planning, advisedly and with clear forecast, those public, provincial, and town libraries in which the United Kingdom has hitherto confessedly been very deficient. The steps which have recently been taken, under Mr Ewart's Libraries Act, are proofs that public attention is now fairly

¹ Letter to Thomas James, printed in *Reliquiæ Bodleianæ* (1703), 278.

purchase.

other libraries or repositories, public or private, transcripts should be obtained, so that the Town Library may become the head-quarters for all seekers into the town history.

If the fund to be expended in book-buying is large, it will be good economy to make, at the outset, a collection of bibliographical works and of catalogues. The learned Gabriel Naudé indicated the advantage of this course two centuries ago (in his curious *Avis pour dresser une Bibliothèque*); and his remark still holds good, that "by this means one may also do a friend service and pleasure, and when we cannot furnish him with the book he is in search of, direct him to the place where he may find a copy." It will also, in many cases, be good economy to draw up and to print, for circulation amongst booksellers, lists of the principal books sought for, and these may be so framed as to serve for a time by way of provisional catalogues. In the search after the best editions of our standard writers, their critics, commentators, and assailants should not be forgotten. Subsidiary works of this kind are often of very troublesome quest; but they are valuable, if not for the light they throw upon their object, at least for that which they reflect upon their age. The silliest commentator on Shakspeare, however little he may illustrate his author, will sometimes afford a very useful illustration of the history of manners, or of the growth of opinion. Whether works which exist both in separate editions and in "collections"—such as, the *Bibliotheca Patrum*, or the *Rerum Anglicarum Scriptores*—shall be purchased only in the one form or in the other; or whether both collections and separate editions shall be sought for, when the latter possess any special claims to attention,—is another question which lies on the threshold of book-collecting for a large library. In general, it may be suggested, that all the great collections which come within the scope of the library to be formed, together with the best Encyclopædias, Lexicons, and Dictionaries of all kinds, should be amongst the earliest purchases. The Transactions of the chief learned societies, and the long sets of important periodicals, should also receive early attention. Books of this description form the true foundation and framework of a library; in addition to their more direct uses, they may render useful help in its subsequent enlargement, and, if neglected at first, there is usually little likelihood that they will be properly cared for at a later period.

In a National Library it will be praiseworthy to bestow pains on the collection of pamphlets, and of the other ephemera of literature; and if the prevailing character even of a provincial or special library be historical, "old tracts" will need to occupy much of the librarian's attention, and not a little space on the shelves. The causes that make them important are often those that make it difficult to obtain them when required.

of books by
legal exaction.

(2.) OF THE COLLECTION OF BOOKS BY LEGAL EXACTION.

The exaction, by legal enactment, of copies of books for deposit in public libraries is both ancient and general. It obtains in the freest and in the most despotically governed countries. But in the former it is usually the relic of a state of things which has almost passed away, and in the latter it seems racy of the soil. Everywhere it is, or it has been, connected with a censorship of the press. In France, the Imperial Library at Paris, and that only, is entitled to a copy of every work published within the empire.¹ In Belgium and in the Netherlands the deposit of copies is not compulsory in all cases, but is the necessary condition of copyright. In Sardinia the Library of the University of

Collection
of books by
legal exaction.

Turin is entitled to a copy of every book printed within the kingdom. In Tuscany every public library enjoys a similar right as respects books printed within the city, and the prefecture, in which it is placed. By the law of Sicily, the University Library at Palermo is entitled to a copy of every book printed in that city; and by that of Naples, four copies of every book printed in the capital must be delivered, two for the *Borbonica*, one for the *Brancacciana*, and one for the University Library. In Rome the printers are enjoined to send five copies to the Master of the Sacred Palace, who is to keep one in his office, to deliver one to the vicar-general, one to the Vatican Library, another to one or other of two libraries—the Gymnasium or the "Sapienza"—and the remaining copy he is to return to the author. In other parts of the Papal States the practice appears to vary, and the right, where it exists, to be almost inoperative.

By the law of Spain, the National Library at Madrid, as respects the whole kingdom, and the provincial libraries, within the respective provinces, have a right to copies. In Portugal, the National Library at Lisbon,² and the Town Library of Oporto, are each entitled to a copy of every book printed within the kingdom. If we turn to Germany, we find similar enactments to be almost universal, with more or less of modification. The Royal Library at Munich is entitled to two copies of all books printed in Bavaria. The Royal Library at Hanover, and the Library of the University of Göttingen, are each entitled to a copy of every book printed within the Hanoverian kingdom. In the Hanse towns a similar privilege is enjoyed by the town libraries of Hamburg and of Lubeck, but not by that of Bremen. By the law of Hesse-Cassel, two libraries, and by that of Hesse-Darmstadt, three libraries, are absolutely entitled to copies of all books published within the electorate or the duchy, respectively. The library at Fulda, in Electoral Hesse, appears to possess this privilege only with respect to books the copyright of which is secured. In Prussia the Royal Library at Berlin is entitled to a copy of every work published throughout the kingdom, whilst the University Libraries have a similar right within their respective provinces.

In Saxony a practice obtains which is different from all the usages hitherto noticed. The printer or publisher of every book is bound to deliver one copy to the appointed officer, whose duty it is to distribute the books, according to their subject and character, between the Royal Library at Dresden and the University Library at Leipzig. In Switzerland, the Geneva library alone has the copy privilege. At Berne it ceased in 1830. At Zurich it is matter of choice and custom with the publishers, but is not compulsory. By the laws of Denmark, the Royal Library of Copenhagen is entitled to two copies of all books published in the Danish possessions. The three principal libraries of Sweden (at Stockholm, Upsal, and Lund), have each a right to one copy of every work printed in Sweden; but this right does not extend to Norway. In Russia, the Imperial Library of St Petersburg is entitled to two copies of every work published within the empire.

By an act of the congress of the United States of America (31st May 1790), which has been continued and extended by subsequent acts, one copy of every work in which a copyright is secured must be deposited in the state department at Washington.³ There the books remain, and are publicly accessible, under certain regulations. At present they are said to amount to about 10,000 volumes; and the average annual increase appears to be about 400 volumes.

¹ Returns relating to Foreign Libraries, procured through the Foreign Office, and printed in the Commons' Sessional Papers of 1850, 1851, and 1852. These are the authorities for all the statements relating to the exaction of copies by foreign legislation, unless it be otherwise indicated.

Collection
of books by
legal ex-
action.

In England, as early as the year 1609, Sir Thomas Bodley made an agreement with the Company of Stationers, by which it was provided that one copy of every book which they should print thenceforward was to be given to the Bodleian Library, and it appears that this agreement was fairly observed until the breaking out of the civil wars.¹ Long before Bodley's day copies had been exacted for delivery to the licensers of the press; but the first parliamentary enactment by which printers were enjoined to give copies to libraries was that contained in the Sedition Act, 14th Charles II., c. 33. Three copies were to be delivered at Stationers' Hall, one of which was to be sent to his Majesty's Library, and the others to the two universities. By the famous Copyright Act of the 8th of Queen Anne, the exacted copies were increased to *nine*, and by the 41st George III., c. 107 (passed after the Irish Union), to *eleven*. This last-named enactment continued to be in force until 1835. The appropriation of the eleven copies was as follows:—1. Royal Library (*British Museum*). 2. *University Library at Cambridge*. 3. *Bodleian Library at Oxford*. 4. University Library, Edinburgh. 5. University Library, Glasgow. 6. King's College Library, Aberdeen. 7. University Library, St Andrews. 8. Sion College Library, London. 9. *Advocates' Library, Edinburgh*. 10. *Trinity College Library, Dublin*. 11. King's Inns Library, Dublin.

By the 5th and 6th William IV., c. 110, this privilege was abolished, as respects six of the eleven libraries above-named; and a yearly grant of L.3028 was charged upon the Consolidated Fund by way of compensation, to be distributed as follows:—

To the Library of the University of Edinburgh	L.575
... .. University of Glasgow	707
... .. University of St Andrews	630
... .. King's College, Aberdeen	320
... .. Sion College, London	363
... .. King's Inns, Dublin	433

The grant was thus apportioned in accordance with an estimate of the annual value of the books which each library had actually received, on an average of a certain number of years prior to the passing of the act. Thus, the privilege having been enforced with far greater strictness at Glasgow than at Aberdeen, the former university receives more than twice the yearly sum assigned to the latter. As the law now stands, the copy of every book due to the British Museum must be there delivered, irrespectively of any demand. The other four copies are due only after demand, in writing, within twelve months of publication. (54th Geo. III., c. 156.)

The copy-exaction, even within its present limits, has always been obnoxious to the great majority of the publishers, and to no small number of the authors, who have been chiefly affected by it. Those, especially, whether authors or publishers, who own the copyright of such illustrated books as are both extensive and costly, have found the exaction to be oppressive. The popular notion, that this is a tax which falls on the consumer and not on the producer (whatever the force of so questionable an argument), is a fallacious one, although it has been repeatedly put forward under various forms. It is, in truth, a tax which seriously enhances the cost of producing precisely such books as it is most clearly the public interest to facilitate, rather than to impede, and which takes out of the market precisely those customers of whose presence there the producers ought to be most secure. Wealthy universities and prosperous guilds would figure far more appropriately in the list of subscribers to the *Flora Antarctica*, or the *History of Leicestershire*, or the *Birds of Europe*, than in the warehouse-

Collection of books by legal exaction.

book of the Stationers' Company as leviers of literary blackmail. The entire system, indeed, of exacting books without payment, belongs to the period when brain products were at the mercy of every plunderer, and copyright was a passing protection, accorded rather as a concession than as a right.

It is not surprising, therefore, that the law on this point has been largely evaded. Up to the present time, the Library of the British Museum is the only one in whose favour it has been thoroughly carried out; and even there it is only during a very few years that it has been so carried out. In 1854 the total number of books, pamphlets, &c., actually received amounted to 19,578. In order to produce this result, great vigilance and some severity have been needed. But so long as the law remains on the statute-book, it ought unquestionably to be strictly enforced.

At Cambridge, during the seven years from 1844 to 1850 inclusive, the total number of books, parts of books, pieces of music, &c., received by the University Library, was 52,348, or, on the average, 7478 yearly. The number for the single year 1850 was 7830.² At Dublin, during the same seven years, the total number received was 21,260, or, on the average, 3037 yearly. The number for the single year 1850 was 3454. The disproportion between the receipts at Dublin and those at Cambridge is very great; Yet it was given in evidence, on the part of both universities, that agents are employed in London, with instructions to claim every book that is published. Both returns also profess to give the number of articles, not of volumes, that are received.

In addition to the objection which, as it seems to us, may fairly be taken to the principle that underlies the enactment in question, there is another, and a grave one, which applies to the mode of using it, as respects the great majority of the participating libraries. Were all these institutions open to the public as matter of right, not of favour, the public would receive some return for the exaction, though an indirect and an insufficient one. It would still be matter of reasonable complaint that a part of the community is taxed for the benefit of the whole community. It would still be true that a national advantage ought to be paid for out of the national purse. But the Libraries of the Universities of Oxford, Cambridge, and Dublin, are *not* national libraries. Of the whole number under both categories, the British Museum Library is the only one to which admission is matter of clear public right, although, in practice, the regulations of the Library of the Faculty of Advocates, Edinburgh, and those of the Library of Trinity College, Dublin, are liberally construed. If the three University Libraries, and the Advocates' Library, should continue to possess a claim to every book published, reasonable compensation should be made to the publishers, at the public charge. Those libraries should be put on as good footing for its enforcement as that enjoyed by the British Museum. All the privileged libraries should be made accessible, without favour, under known rules. All should be bound to *publish*, in due concert, an accurate and full descriptive list of every publication which they have received. The literary community would thus obtain a better "Publishers' Circular" than has yet existed.

(3.) OF THE COLLECTION OF BOOKS BY DONATION.

Although nothing is more certain than that those who love books are usually very chary of parting with them, yet in all the great libraries we find a considerable number of volumes which have been acquired, sometimes by gift, but more frequently by bequest. Of the 562,000 volumes which are now in the British Museum, no less than

Collection
of books by
donation.

220,000 have been either presented or bequeathed. But even this goodly number would, in all probability, have been greatly increased, if, some forty years ago, there had been less narrowness of view as to the necessary qualifications for what some have called the "blue ribbon of literature"—a trusteeship. This was the great object of ambition, both to Richard Gough, the author of the *Sepulchral Monuments of Great Britain*, and to Francis Douce, the author of the *Illustrations of Shakspeare*. Both of them had made valuable additions to English literature; both of them possessed fine libraries, especially rich in British topography and history; but neither of them was either a peer or a placeman. Both fortunately bequeathed their libraries to the University of Oxford, where they are worthily lodged; but of their comparative usefulness to the public, as they are, and as they might have been, not a word need be said. Since those days, it has happily become apparent, even to the official mind, that the dignity of the trusteeship is not diminished by being shared with a distinguished geologist or a great historian; and the list is now graced by the names of Murchison, Buckland, Hallam, and Macaulay, as well as by those of dukes and chancellors.

Worthy Bishop Huet, in his amusing *Commentaries*, has told us, in pathetic terms, of the regret with which he saw the fine library of the President de Thou disposed of in bulk (notwithstanding the pains with which the illustrious owner had entailed it as an heir-loom); but when, at a later period, it was sold in detail, part of it, he adds, "came into my possession; and . . . from this example I was led to be sensible of the certain destruction that awaited my library, unless I should make careful provision for preventing it. Having long and attentively revolved this in my mind, it appeared to me the best plan for keeping it entire, in perpetuity, to present it to some stable society of persons bound to the rules of a religious life."¹ Of all "stable" societies, the good bishop, as the result of his long wanderings, fixed on the Jesuits, and his "perpetuity" proved to be less than a century, although a portion of his collection and the good fortune to be subsequently incorporated (as a portion of the noble library of De Thou had previously been) with the Imperial Library of France.

Sometimes accident and caprice, at others shrewd observation and insight, will determine the fate of collections, as far as human arrangements can determine anything; but it is obvious that those libraries will be likeliest to have a good share of such acquisitions as combine evident care of the books they already possess with a wise liberality in their arrangements for access and profitable use.

There is, however, a class of books—both important and numerous—with the appropriation of which accident and caprice should never have anything to do; those, we mean, which have been printed at the national expense. Yet usually, in this country, the distribution of these books has been pre-eminently capricious. They are under the control of various departments and functionaries. Intelligible rules have rarely been laid down for disposing of them, notwithstanding that the cost of their production to the country is very considerable; and when there has been the semblance of such, they have rarely been adhered to.

Amongst the works thus produced, which are especially valuable in libraries, may be mentioned, the collections of public documents, and of historical materials (such as the *State Papers of the reign of Henry VIII.*, and the *Monumenta Historica Britannica*); narratives of Voyages of Discovery, and Reports of the naturalists, and other scientific officers connected with them; Collections of Astronomical Observations; and, generally, the various publica-

tions connected with the Ordnance Surveys, and the Geological Survey of the United Kingdom. Some of these publications are under the control of the Home-Secretary, others under that of the Board of Admiralty, and the Board of Ordnance. As respects none of them have systematic rules of distribution been adopted; and it would be easy, but can scarcely be necessary, to cite instances of the capricious absurdity with which they are sometimes granted to one library, and refused to another, under circumstances precisely similar.

The Reports and Papers of both Houses of Parliament are also most important acquisitions for public libraries. The select committee on the subject of the dissemination of those of the House of Commons, appointed in 1853,—to preside over which, with self-denying perseverance, under all the discouragement of failing health, was the last service of a true public servant, the late Henry Tufnell,—strongly recommended a *free* distribution of these documents to all libraries which united the two conditions of secured permanency and unrestricted accessibility; but the recommendation has yet to be carried out. No objection to it has been advanced which is not a proven fallacy, and the measure needs only to be taken up by a vigorous hand in order to its proper settlement.

(4.) OF THE COLLECTION OF BOOKS BY INTERNATIONAL EXCHANGE.

Collection
of books by
international
exchange.

Occasional, and sometimes munificent, exchanges of the literary and scientific productions of different countries are by no means of recent origin, but until very lately they have been accidental rather than systematic; and our own country has been a laggard in their encouragement. There is a Treasury minute of 1832, in which "the Chancellor of the Exchequer informs the board that there is the prospect of an arrangement being made . . . with the government of the King of the French, by which an interchange of all new literary publications will be secured for the use of the library of the British Museum in the one country, and the Bibliotheque du Roi in the other."² But the "prospect" has remained a prospect, except only as regards the very useful interchange of public documents between the libraries of the respective legislatures. It appears to have been about this time that the attention of Mr Alexander Vattemare was attracted to the subject of international exchanges of books, and there is abundant evidence that he has given important help in a good work. In 1853 Mr Vattemare addressed to the "convention of librarians," which met in New York, a report, in which he enumerated upwards of 130 public libraries and other establishments which had "participated in the benefits of the system of exchanges;" and stated that in this way no less than 61,000 books and pamphlets had been distributed, during five years, by his agency, in the United States and in Europe.³ Two years later, the Regents of the University of the state of New York, in presenting to the legislature their annual report for 1855, as trustees of the State Library, spoke in high terms of commendation of the results in that state of Mr Vattemare's exertions.⁴

A similar agency, on a much larger and rapidly increasing scale, has been recently established by the Smithsonian Institution at Washington. On this head it is stated, in the eighth annual report (1854), that "the institution is now the principal agent of scientific and literary communication between the Old World and the New. Its system of exchange is established on a reliable basis, namely, that of the publications of the institution itself. . . . The importance of such a system, with reference to the scientific

Construction, &c., of public libraries.

character of our country, could scarcely be appreciated by those who are not familiar with the results which flow from an easy and certain intercommunication of this kind.¹

(5.) THE CONSTRUCTION AND FURNISHING OF BUILDINGS FOR THE RECEPTION OF PUBLIC LIBRARIES.

The first difficulty which a committee, charged with such a duty, has usually to grapple with is, to reconcile the frequently conflicting claims of *site* and of *form*. A public library, and above all a Town Library, needs a site as central as can be obtained. Any library which is to be adequately kept up should be of such form as shall admit of easy and considerable enlargement, without entailing the necessity of re-arranging the existing contents. Either a cruciform, a polygonal, or a circular building will, more or less, meet these requirements, provided always, that additional space has been preserved to meet the contingency of extension, or can be readily obtained. But this is precisely the condition which it is most difficult to secure in the centre of a town. When one or the other of these advantages must be foregone, it will often, we think, be good economy to make some sacrifice in site rather than forego the benefit of an easily expandible *plan*. The circular, or polygonal, plan is best of all, because the most favourable to completeness and permanency of arrangement, in union with gradual and indefinite extension; and it is quite certain that no inconvenience of position will prevent a public library from being well frequented, if it be rich in books, and liberal in its regulations. This premised, we proceed to suggest other considerations which should be borne in mind in planning a library which is to be permanent, and for which adequate funds are at hand.

1. The site must be dry and airy; the building (whatever its form) isolated; and, if placed in a great thoroughfare, it should be set back as much as possible.

2. The building should be fire-proof. To this end, other materials than brick, stone, iron, and slate, should be very sparingly admitted into its main structure. Such timber floors as may be used in any special apartments should be embedded in stucco, upon a stone flagging, or upon brick arches.

3. The ground-floor should be vaulted, and in all the external walls there should be ample apertures and channels for ventilation. If the building be extensive, large water-pipes (fire-mains) should be carried along the roof.

4. Whenever practicable, light should be obtainable from all sides, but should be provided, as much as possible, from cupolas, or lantern-lights, which obviously favour the appropriation of the largest amount of wall-surface for book-shelves within a given area.

5. The principal rooms destined for the reception of books should be of such proportions, and be so constructed, as to admit of the greatest possible proportion of the contents being seen at one view. Every shelf should be accessible without the use of steps or ladders. By providing light galleries of perforated iron, with breast-high railings and with spiral staircases at each angle of the room, this advantage may be secured even in the loftiest rooms. If, for example, the library be 35 feet high in the clear, four tiers of galleries, placed at intervals of about 7 feet, would admit of every book being instantly accessible without any loss of space.

6. The reading-room should invariably be separate from the rooms appropriated to the main collection of books; but it should be as much in the *centre* of the building as possible, and should be shelved for the reception of books of common reference (especially of such as form what may be fitly termed the bibliographical apparatus of a library). One or more smaller and adjacent rooms should be assigned for the use of such readers as need special facilities for collation, copying, and other like pursuits. The reading-rooms should be provided with a series of shelved closets, for the reception of books which are in continuous use from day to day. Such shelves may be lettered alphabetically, and the books placed according to the names of the readers who retain them, as has long been the practice in the British Museum.

7. There must be an ample provision of work-rooms contiguous to, but distinct from, the rooms appropriated to books and those

appropriated to the readers. In any extensive library the following separate rooms will be found essential to the thorough working and good order of the establishment:—(1.) A receiving and unpacking room. This should have a separate entrance. (2.) A stamping and registering room. (3.) A cataloguing and account-keeping room. (4.) A book-binding room. If the binding be done within the library building, this room should, of course, communicate with the workshop; but if otherwise, there should still be a small separate room devoted to the business connected with the binding. (5.) A board-room, or "committee-room." (6.) A librarian's room, which, in a large library, should have its waiting-room attached. (7.) Rooms for assistant librarians, &c., according to the extent of the establishment. (8.) Cloak-rooms, lavatories, &c., in similar proportion. In a great library, an ante-room, so placed as to afford convenience for the necessary and thorough cleansing of the books from time to time, will also repay its cost. Even in a small library, the provision of good and ample work-rooms will be found to be true economy in the long run. If the regulations of a library, whatever its extent, prescribe residence within the walls to a librarian or other officer, his apartments should be isolated from the main building.

8. It may now be assumed as a settled point, that a library of any size may be safely warmed either by open fire-places² properly constructed, or by hot-water pipes carried throughout the building. If the former are used, there are ample means and appliances for ensuring their security. If the latter, they should be placed in grated channels provided in the fire-proof floors, at a distance of at least 3 feet from the nearest books. Other pipes should be carried round or near to the lantern-lights and other extensive glazed surfaces. The boiler-house should be separate from the library building, and the circulation of the heated water should be unintermittent.

9. It may also be taken to be another point which experience has demonstrated, that gas may, with perfect safety, be introduced into a properly constructed library. The gas-fittings should always include tubes for carrying off from the burners the vapours produced by its combustion. The inner tube may be of copper, and the outer one of opaque glass; and these tubes may, with equal facility, be made pendant from the ceilings, or projecting from the walls; or, on the other hand, the lights may all be placed outside of the building,—a method which may be seen in very successful operation at University College, London, and elsewhere.

10. Book-presses may be made either of wood, as is usual, or the shelves may be of enamelled slate, and the backs and uprights of galvanized and perforated rolled iron. Whatever the material, the shelves should always be moveable, so that they may easily be adjusted to books of any size. The cases should be perfectly plain and smooth within, having neither projecting ornament near the shelves, nor any cavity at the sides. The lowest shelf should be at least 6 inches above the level of the floor, and there should be a clear space between the backs of the cases and the walls against which they stand. It will also be a good plan to make all the presses and their several parts of uniform dimensions, so that they may be transferable and interchangeable if necessary. All shelves intended for choice books should be covered with padded leather. Glazed table-cases, with sloping frames, should be provided for the exhibition of rare and curious books, autographs, and the other select treasures of a library.

11. For books of unusually large dimensions, either special shelves, on which they can lie flat, or "trays" constructed in the table-cases, should be fitted up. In a great library, other table-cases or tables should be fitted up with similar "trays," or with drawers in tiers, for the preservation and due arrangement of the catalogue titles or slips.

12. Reading-rooms should be provided with a special desk for catalogues, large enough to contain several sets, and with a good supply of reading-frames of various sizes. The use of these protects books of large dimensions from injury, as much as it promotes the convenience of readers. A very good form of reading-table and frame conjoined has recently been patented in the United States, by Mr Folsom of Boston, and will be found figured in the *New York Literary Gazette* of 1st June 1854. It is especially suitable for holding books of prints. Book-barrows or trucks, the tops and end rails of which should be covered with padded leather, are also very serviceable in a library.

(6.) OF THE PLAN AND PREPARATION OF CATALOGUES. Plan and preparation of catalogues.

An accurate catalogue of some sort, well kept up, is a

¹ *Eighth Report of the Regents of the Smithsonian Institution* (1854), 37–50.

² See the valuable evidence given by Mr Braidwood, superintendent of the London Fire Brigade, before the Commons Committee on the New Record Offices.

Plan and
preparation
of
catalogues.

cardinal point in the good management of a library. The question, *on what plan* the catalogue should be made, is not a very momentous one; yet very few questions of a literary kind have given rise to so many varieties of opinion. Few, it may be added, have been discussed more elaborately and sedulously by those who have striven to master them, or more flippantly by those who have been content to skim their surface.

The catalogues of public libraries have usually been either alphabetical or classed. Each plan has its special advantages and disadvantages. If the alphabetical arrangement be adopted, the cataloguer has to choose between an alphabet of authors and an alphabet of subjects. The first has the merit of being easy of construction, familiar in use, and eminently serviceable to all such readers as want the known books of known authors. But here its merit ends. For a reader who is in quest of *all* the books, known or unknown, avowed or anonymous, which the library contains upon a given subject, or section of a subject, a catalogue according to authors' names is almost useless. It may, indeed, lead him to all the works with which he is already more or less acquainted, but will do this only after a great expenditure of time and toil in searching volume after volume throughout the alphabet. In a great library this expenditure will be trebled, if (as has been too commonly the case) the names of authors are mixed pell-mell with the headings of anonymous books in a single alphabet. There are subjects on which the best books extant are anonymous. It is probable that every great national library contains more works without authors' names than with them. Of these anonymous books, a considerable proportion will doubtless belong to authors whose names are either known to, or conjectured, more or less plausibly, by, the learned bibliographer. But if conjecture be allowed to govern the *place* of a book in a catalogue, all reliability on it ceases.

If, on the other hand, an alphabetical arrangement according to the subject-matter of books be preferred, it becomes much easier to deal with the anonymous works. It is certain, also, that a large number of useful references are thus put at a glance before the student; and the plan exacts no previous acquaintance with systems of classification. But these merits have to be weighed against grave defects. Of necessity, such catalogues must deal rather with the phraseology of title-pages than with the real subject-matter of books, and must therefore fail to bring under one view all, or any near approximation to all, the books which the library contains on a given topic. In some cases, one word will have several distinct significations, and then the reader's search is obstructed by matter foreign to his purpose; in others, a subject is expressible by several synonymous, or at least convertible terms, and then all these must be turned to before he can be certain that he has the information of which he is in quest.

The schemes of classification which have been at various times propounded are multitudinous. No author has attempted to describe them all. Collections, however, more or less extensive, have been made by Peignot (*Dictionnaire raisonné de Bibliologie*, 1802); by Achard (*Cours Élémentaire de Bibliographie*, 1806); by Mr Hartwell Horne (*Outlines for the Classification of a Library*, 1825); by Sir John William Lubbock (*Remarks on the Classification of Human Knowledge*, 1834); by Brunet (*Manuel du Libraire*, 4ème édition, 1845, *Introduction*); and by M. Albert (*Recherches sur les Principes Fondamentaux de la Classification Bibliographique*, 1847).

All the schemes which have been propounded, from Gesner's day down to our own, may be gathered into one or other of two groups, by far the largest of which, whatever its other merits, is essentially unsuited to the business of a library. The schemes which belong to the first group aim

at a systematic and consecutive arrangement of all human knowledge, in accordance with some theory, either of the powers and functions of the mind itself, or of the order and succession in which the phenomena of the material world may be conceived to present themselves to its contemplation. The schemes which belong to the second group, with far humbler pretensions, seek but to sort, after some handy and convenient fashion, the instruments of knowledge for daily use. In the former case the system-maker aspires to solve some of the knottiest problems which have ever puzzled metaphysicians. In the latter case, he is content if he be found to have facilitated the buying and selling, the shelving and finding of books, by all who handle them.

At the head of the second group, Gabriel Naudé has, perhaps, the best claim to stand. The general character of his scheme is indicated in the *Avis pour dresser une Bibliothèque*, which he published in 1627, although it was first developed in the *Bibliotheca Cordesiana*, which did not appear until 1643. Naudé deserves the credit of having been a pioneer in the right path; but the real originator of the system which has the fairest claim to be styled a bibliographical one, was Ismael Bouillaud, the compiler of the Catalogue of the Library of De Thou. Bouillaud's Catalogue was not published until 1679, a year after the appearance of the elaborate *Système Bibliotheca Collegii Parisiensis Societatis Jesu* of Father Garnier; but it had been written several years before it was published, under the editorial care of Quesnel. Bouillaud makes no display of his ingenuity, by adding new classes to those of his predecessors, nor of his erudition, by coining far-fetched and sonorous names for the old ones; but he lays a firm grasp on five comprehensive classes:—I. *Theology*; II. *Jurisprudence*; III. *History*; IV. *Philosophy*; V. *Literature*; and brings all the books with which he had to deal under one or other of these main divisions. This scheme has the advantages of simplicity, facility, and expansibility. All its main classes, with the exception of *Philosophy*, possess well defined limits. All may be adjusted, by modifications of mere detail, to the extent and character of the particular library to which they have to be applied. It was to be expected, therefore, that the plan would win the favour, not only of librarians, but of men who were at once eminent booksellers and eminent bibliographers, such as Marchand, Gabriel Martin, Debure, and Brunet. Each of these men improved some or other of its details. Most of them agreed in substituting the class *Sciences* and *Arts* for the class *Philosophy*, and in employing the latter term as a subdivision of the former. The class *History*, too, was usually made fifth in order, instead of being third. But the substance of the scheme remained unaltered; and, in course of time, it came to be embodied in an unrivalled series of catalogues, which are classics in their kind.

In this country the Paris system is best known in the form which Mr Hartwell Horne gave to it when cataloguing the fine library of Queen's College, Cambridge; and when preparing his *Outlines for the Classification of a Library*, which were submitted to the trustees of the British Museum in 1825. Mr Horne's modifications are bolder than most of those which have been adopted by French bibliographers, and some of them possess unquestionable merit. Four out of the five principal classes he leaves intact. The class *Sciences* and *Arts* he breaks up into two, the first of which he designates *Philosophy*, and the second *Arts and Trades*. The six classes thus formed he ranks in the following order:—I. *Theology or Religion*; II. *Jurisprudence*; III. *Philosophy*; IV. *Arts and Trades*; V. *History*; VI. *Literature*. In the subdivisions he introduces several changes. He removes the section "History of Religions" from the class *History*, and places it in *Theology*; and, in like manner, transfers the "History of Literature" from the class *History* to the class *Literature*. The vast and rapidly in-

Plan and
preparation
of
catalogues

Internal regulation, &c., of libraries. creasing literature of politics and commerce is joined to ethics, and is made a section of the class *Philosophy*, under the general designation of "Moral and Political Philosophy." The first-named change is, we think, one of very doubtful expediency. It tends to confound the history of the church with the history of dogmatic theology (obvious as is the fact, that between such works as Fuller's *Church History of Britain*, and Wall's *History of Infant Baptism*, or Heylin's *History of the Sabbath*, the resemblance is but verbal). If, however, there should seem, on mature examination, a balance of advantage in favour of this course, the alteration, it may be thought, ought to involve the transfer of our military history to the "Art of War," and of our parliamentary history to "Political Philosophy." But, be this as it may, Mr Horne's scheme, taken as a whole, is probably one of the best which is extant, and with it we must close our brief glance at a wide subject.

(7.) OF THE INTERNAL REGULATION AND FINANCIAL ECONOMY OF LIBRARIES.

Before they are placed on the shelves, the books of a public library need not only to be catalogued, but to be stamped and press-marked. The best mode of stamping books is by an embossing-press; and the stamp should be applied to every plate and every map, as well as to the title-page and the first and last leaves of the volume. The press-mark, or symbol, which indicates the place of a book on the shelves, should appear both on the outside and inside of every volume. If lettered on the binding itself, it is almost indelible, and thus involves extra trouble and cost, in the event of a re-arrangement of the books; but this plan has greatly the advantage in point of appearance, and if care be used, the proportion of books which may need removal will be very small. In libraries of no great extent, progressive numbers are commonly used; in large libraries it is more usual to give numbers to the several presses, letters to the shelves, and numbers again to the volumes on each shelf. Thus 18 D. 12 will denote the 12th book on the fourth shelf of press 18. There is no necessity to class books on the shelves with the minuteness of detail which is requisite for a good catalogue, but the main divisions of the catalogue should be carried out in the practical arrangement. And by allotting each class a *surplus* number of presses, provision may be made beforehand for considerable additions, in continuous order, without either interrupting the succession of the classes, altering the press-marks of the books already catalogued, or resorting to the unsightly expedient of intermingling empty shelves with full ones. Thus, for instance, if the order of the classes be that adopted by Mr Hartwell Horne, and there be in the library enough books in the class "Theology" to fill, say twenty-five presses, the books in "Jurisprudence" may begin in the twenty-sixth press, but that press may be numbered "51," instead of "26." The books *added* to the class "Theology" will, of course, belong to "press 26," and may be placed in any part of the library until they have amounted to an entire pressfull.

Experience has shown that the rapid service of readers may be greatly promoted by requiring that the demand for a book shall be written, not verbal, and that the reader, in ordinary cases, shall be expected to look in the catalogue, and copy from it the press-mark of the book he applies for. Another means of facilitating the supply of books to readers, is to affix to every press in the library a brief synopsis of its contents. If a reader requires the 120th volume of a long set, to give its precise press-mark would be exacting an idle waste of time. By placing a "tablet" to each press, an attendant may light on any such volume in a moment.

Those in use in the Manchester Free Library, are printed and varnished, and are placed breast-high in front of each press.

An accurate system of registration and book-keeping is of the first importance to the good working of a public library. The following may be regarded as among the appliances of this kind which are indispensable. In many libraries others will be necessary for special purposes. The account-keeping, which belongs to a *lending* library, in particular, will be referred to hereafter:—

1. An *Accession Catalogue*, or Register, indicating the date of each acquisition, and how it was acquired.
2. A *Donation-Book*, for more ample descriptions of all gifts than are needed in the Register, in which the briefest indication will suffice.
3. A *Shelf Catalogue*, in which every book is entered in the shortest form, press by press, and shelf by shelf. This catalogue should be so prepared as to admit of its being used in the way of "stock-taking" from time to time.
4. A *Binding-Book* for entry of all books delivered to the binder, and for the due chequing of their return.
5. A *Report-Book* for entering the daily returns of issues to readers. These issues should be classed in the order which is used in the general arrangement of the library.
6. A *Suggestion-Book* for the insertion by readers of books deemed desirable for addition to the library.
7. A *Ledger and Cash-Book* of the ordinary mercantile kind, for receipts and disbursements.
8. An indexed *Minute-Book* for the board of management, or other authorities.

If the admission to the library be by way of ticket, as at the British Museum, an "Admission-book" will be required for the registration of readers, and this book should, of course, have an alphabetical index. If the library be open to all comers, there may still be a sort of "Day-book," in which readers should be requested themselves to enter their names and addresses. On behalf of the more free system of admission, there may be adduced its wide-spread prevalence on the Continent, and the extensive testimony which has been recently borne by foreign librarians and other officers to the absence of any noticeable abuse or mischief thence arising.¹ On the other hand, it has been alleged, and (at all events, until a very late period) with much appearance of justice, that the greater facilities and freedom which it has been usual to afford in the principal British libraries to readers, when once admitted, warrant the exaction of *some* preliminary introduction, by way of guarantee of their respectability.

Of late, however, the operation of Mr Ewart's Act in some of the largest towns in England has brought evidence to bear on this question which is wholly new. It has been proved by experience, that an aggregate issue of 200,000 volumes may be made in one library of a densely peopled city, on the principle of unrestricted admission, without the loss of a single book. It cannot, of course, be asserted that such experience is precisely parallel, in any particular, to the case of a great national library like that of the British Museum. The wear and tear which, by this plan, falls on books that chance to be in popular demand is enormous, and of itself would necessitate restrictions for the protection of such as are not easily replaceable. The true deduction from this recent experience seems, on the whole, to be, that the metropolis, and every other great city and town in the empire, should have its free libraries, open to all who choose to enter; and that the regulations of the old libraries may, with perfect safety, be relaxed under judicious management; but it does not follow that the same rules will suit all libraries.

The applicability of Mr Ewart's Act of 1855 (18th and 19th Vict., c. 70) extends, first, to all municipal boroughs, the po-

¹ On this point, the returns relating to Foreign Libraries, obtained through the Foreign Office (at the instance of Mr Ewart's Committee), and presented to Parliament in the years 1850, 1851, and 1852, contain abundant and conclusive evidence.

Internal
regulation,
&c., of
libraries.

pulation of which, at the last Census that shall have been taken, shall have been found to exceed 5000 persons; secondly, to all districts of like population having an Improvement Board; thirdly, to all parishes of like population; and fourthly, to any two or more neighbouring parishes having an aggregate population of like extent. In order to its adoption, a public meeting of rate-payers must have been duly convened, and the proposition must have been voted for by *two-thirds* at least of the persons there present. If the proposition be so carried, the act comes at once into operation. The Town Council, or Improvement Board, or Parish Vestry, as the case may be, become empowered to levy a library rate, not exceeding one penny in the pound on the rateable value of the assessable property in the borough, district, or parish. The library rate may be applied wholly to the establishment of a library, or partly to a library and partly to a museum. The management and control of the libraries and museums thus established is, in a city or borough, vested in the Council; in a district, in the Improvement Board; in a parish, in Commissioners to be named by the Vestry. Such commissioners must be rate-payers, and in number not less than three nor more than nine. The Council, or other body, have powers to provide books, newspapers, maps, specimens of art and science, and all other needful matters; and to employ all requisite officers and servants. It is further enacted, that admission to all libraries and museums, established under the act, shall be free of all charge.

Other acts (17th and 18th Vict., c. 64, and 18th and 19th Vict., c. 40), differing chiefly in their local machinery, make similar provision for Scotland and for Ireland; but in Scotland a poll may be demanded by any five qualified voters, which poll must be taken within two days of the meeting at which it shall have been demanded.

Almost all the libraries which have been founded under the act include reference departments, and lending departments. In the lending department attached to the Free Library of Manchester, no person is allowed to borrow a book from the library without first obtaining the signatures and addresses of two rate-payers, whose names appear on the Burgess Roll of Manchester, or on that of Salford, and who, by a voucher, undertake to replace any book which shall be lost or materially injured by the person borrowing.

The indispensable account-books of a lending library will be—1. A *Register-Book*, in which to enter the number and short title of every book borrowed, and the name and address of the borrower. This register should have a column for the progressive number of each day's issues (such number to be marked in the book borrowed, upon a proper "issue page" inserted in every volume which the

lending library contains), and another column in which to mark the due return of the book so entered. 2. An *Application and Guarantee Book*, in which every applicant is entered, with the name and address of his "guarantee," the date of application, and the date and number of the ticket issued to him. Such book will need two alphabetical indexes—(1), borrowers; (2), guaranties. 3. A *Shelf Catalogue*. 4. A *Fines-Book*, in which to enter all books lost or injured, and the sums paid in compensation.

With careful superintendence, uniform enforcement of the rules, and a strict *periodical* calling-in of all books lent, for due examination, it will be found that a lending library may be successfully worked on the most liberal terms of access, in the most populous towns, with a loss so inconsiderable (the inevitable wear and tear of an enormous issue, of course, excepted), as to be unworthy of notice. In the case of the Manchester Free Library, the lending issue, in three years, was 236,320 volumes. The total loss to the library was *ten* volumes, the collective value of which did not exceed one and twenty shillings. If the peculiarly *moveable* character of a considerable portion of the population of manufacturing towns be taken into account, such an experience may well be deemed encouraging.

One of the most striking changes in regard to the working of *popular* libraries which has marked the onward course of years, is unquestionably the disappearance of restrictions as to the class of books admitted, which were once of almost universal prevalence. Books on theology, and books on politics, were, not very many years ago, tabooed, by express rule, from the shelves of not a few public libraries, and especially from such as were intended for the humbler classes of society;—in other words, precisely that mental nutriment which meets the highest spiritual wants, and also that which deals with the most urgent material necessities of men, were excluded. *Not* to exclude them involves, unquestionably, the circulation of books in which more or less of error is mingled with more or less of truth. An eminent statesman has supplied, in statesman-like words, an answer to the objection:—

"Why not," said Lord John Russell, at a public meeting on the 17th Nov. 1855, "permit the free circulation of truth and error;—leave to truth its own all-sufficient armour, and to error its own stratagems and delusions,—leave argument to be met by argument, assertion by inquiry? If the just cause suffer for a time, if human credulity embraces error with ardour, and is cold as ice to truth, we may yet rely that the light of free discussion will in time disperse the mist of false opinions,—that, however slow the process, the test of free examination will in time separate the dross from the genuine ore." (E. E.)

LIBRARIES (HISTORY OF).

In almost all parts of the world where civilization has made any considerable progress, traces may be discovered of the existence of libraries. At the period of the Spanish invasion of South America, for instance, emblems or pictorial representations were employed instead of writing; letters being wholly unknown: in Yucatan and Honduras there were books composed of the leaves of trees; and in the kingdom of Mexico the natives had, by way of *library*, histories and calendars, in which they painted such things as had proper figures by their natural representations, and such as had none, by means of various other characters, so that they expressed in this way whatever they pleased.¹ This may be considered as a library in its earliest stage; for all those that are described as having belonged to the ancients were

composed of rolls, which, though different in form from our books, supplied the place of them, and, when collected, constituted a library, even in the modern acceptance of that term.

I.—ANCIENT LIBRARIES.

As the earliest form of the graphic art appears to have consisted in inscribing or engraving characters on stone, metal, wood, or other durable substance, so the first public libraries were composed exclusively of archives deposited in the temples, that the acts relating to history and public law might there be preserved. This will be found to hold true almost universally. Men invariably begin with what is ab-

¹ Herrera, decade ii., book ix., c. 4.

libraries.

Ancient
Libraries.

solutely necessary to their well-being; and it is only after the lapse of a long interval that time and the progress of improvement add the useful to the necessary, and the ornamental to the useful.

Libraries
of the
Egyptians.

Osymandyas, one of the ancient kings of Egypt, is said to have been the first who founded a library, and established it in a division or compartment of the edifice which has sometimes been called his palace, and sometimes his tomb. On the entrance was inscribed the words ΨΥΧΗΣ ΙΑΤΡΕΙΟΝ, *The Dispensary of the Soul*; whilst the sculptures upon the walls represented a judge, with the image of truth suspended from his neck, and many books or rolls lying before him. Such is the account given by Diodorus,¹ who had himself visited Egypt, but who merely mentions the edifice, without giving us any information as to its contents. It probably contained works of very remote antiquity, and also the books accounted sacred by the Egyptians, all of which perished amidst the destructive ravages that accompanied and followed the Persian invasion under Cambyzes.

Both Wilkinson² and Champollion³ identify with the building referred to by Diodorus the well-known monument,—usually designated the “Memnonium,” but preferably the “Ramesium,”—on the door-jambs of one of the inner halls of which may still be seen representations of Thoth, the inventor of letters, and the goddess Sakh, his companion, with the titles “Lady of Letters,” and “President of the Hall of Books.” In a certain sense, this monument is familiar to thousands of persons who have never visited Egypt, as from it was obtained that “Head of the young Memnon,” which has long been so conspicuous an object in the Egyptian Gallery of the British Museum.

There was also, according to Eustathius and other ancient writers, a fine library at Memphis, deposited in that temple of Phtha, from which Homer was idly accused of having stolen both the *Iliad* and the *Odyssey*, and afterwards published them as his own. From this charge, however, the bard has been vindicated by various writers, and by different arguments.

But the most superb library of Egypt, perhaps of the ancient world, was that founded by Ptolemy Soter, at Alexandria, and enriched by successive sovereigns of that country. About the year B.C. 290, this Ptolemy, a learned prince, founded an academy at Alexandria, called the Museum, where there assembled a society of learned men, who were devoted to the study of philosophy and the sciences; and for their use he formed a collection of books, the extent of which has been very variously computed.⁴ Josephus puts a speech into the mouth of Demetrius Phalereus, as addressed to Ptolemy, in which he says, that there were about 200,000 volumes in the library, and “that in a little time there would be 500,000;” but the entire story—like that as to the origin of the Septuagint—is a fable, having no sort of authority. Demetrius Phalereus was never librarian of the Alexandrian Library. Ptolemy Philadelphus, an equally liberal and enlightened prince, collected great numbers of books in the temple of Serapis, in addition to those accumulated by his father, and at his death left in it, according to the statement of Eusebius, about 100,000 volumes. He had agents in every part of Asia and of Greece, commissioned to search out and purchase the rarest and most valuable writings; and amongst those which he procured were the works of Aristotle, purchased of Neleus.⁵ The measures adopted by Ptolemy

Philadelphus, for augmenting the Alexandrian Library, were pursued by his successor Ptolemy Euergetes, with unscrupulous vigour. He caused, it has been said, all books imported into Egypt by foreigners to be seized and sent to the academy or museum, where they were transcribed by persons employed for the purpose; upon which the copies were delivered to the proprietors, and the originals deposited in the library. He borrowed of the Athenians the works of Sophocles, Euripides, and Æschylus; caused them to be transcribed in the most elegant manner possible; retained the originals for his own library; and returned to the Athenians the copies which had been made of them, with fifteen talents⁶ for the exchange. As the museum, where the library was originally founded, stood near the royal palace, in the quarter of the city called Bruchion, the books, it is supposed, were at first deposited there; but when this building had been completely occupied with books to the number of 400,000 volumes, a supplemental library was erected within the Serapeum, or temple of Serapis; and the books there placed gradually increased to the amount of 300,000 volumes; thus making, in both libraries, a grand total of 700,000 volumes.

The Alexandrian Library continued in all its splendour until the first Alexandrian war, when, during the plunder of the city, the Bruchion portion of the collection was accidentally destroyed by fire, owing to the recklessness of the auxiliary troops. But the library in the Serapeum still remained, and was augmented by subsequent donations, particularly by that of the Pergamean Library, amounting to 200,000 volumes, presented by Mark Antony to Cleopatra; so that it soon surpassed the former both in the number and in the value of its contents. Seneca affirms that the Alexandrian Library was rather to be considered a pompous spectacle for the public, than a place for the studies of the learned.⁷ At length, after various revolutions under the Roman emperors, during which the collection was sometimes plundered and sometimes re-established, it was utterly destroyed by the Saracens, under the orders of the Caliph Omar, when they acquired possession of Alexandria, A.D. 642. Amrou, the victorious general, was himself inclined to spare this inestimable treasury of ancient science and learning; but the ignorant and fanatical caliph, to whom he applied for instructions, ordered it to be destroyed. “If,” said he, “these writings of the Greeks agree with the Koran, or book of Allah, they are useless, and need not be preserved; if they disagree, they are pernicious, and ought to be destroyed.” The sentence of destruction was executed with blind obedience. The volumes of parchment, or papyrus, were distributed to the four thousand baths of the city; and such was their incredible number, that six months were scarcely sufficient for their combustion.⁸

This, at all events, is the received account of a memorable event, and, although often questioned, it has never been satisfactorily refuted. But it should be borne in mind, that the identification of the library destroyed by Omar with the library which had been established, and *perhaps* restored in the Serapeum, is wholly conjectural. The Temple of Serapis had itself been demolished two hundred and fifty years before by Theophilus, Archbishop of Alexandria, and it is certain that the library was then pillaged if not destroyed. Orosius has recorded the feelings of indignation aroused, towards the close of the fourth cen-

⁸ Gibbon (*Decl. and Fall of the Roman Empire*, vol. ix., p. 440) has endeavoured to disprove the positive account given by Abulfaragius, by means of negative arguments. It should be considered, however, that the direct and positive statement of an historian of such unquestionable credit as Abulfaragius, cannot be set aside by arguments of a negative and hypothetical character.

Ancient
Libraries.

tury, by the sight of the still empty shelves. (*Nos vidimus armaria librorum, quibus direptis, exinanita ea a nostris hominibus, nostris temporibus memorant.*¹) Besides the two great libraries which have been already described, Alexandria possessed a third in the Sebasteum, or Temple of Augustus, and a fourth of much later date than the others, attached to its famous "School." If the last named collection were the object of Omar's fanaticism, the loss to learning may have been less severe than has usually been imagined.

Libraries
of the He-
brews.

The ancient Greeks, whose poetry has been to us the primary source of all our profane literature, had as yet no other theology than the system which resulted from observations made on the theory of the different parts of nature, at a time when the Hebrews, in the books of Moses, cited by one of those ancient historians who copied the chronicles,² read the account of the creation, and, along with it, a summary of the traditions of fifteen centuries of continuous history. These books composed the first collection of the Hebrews; but subsequently this people, like most others, had their archives. Those which Herod caused to be burned, with the intention of destroying the monuments of the ancient families, appear to have reached as far back as the very origin of the nation.³ But though he consigned the public records to the flames, those of individuals were beyond his power, and afterwards served to re-establish the history of this subjugated people. There also existed libraries, properly so called, in Judæa. One in particular is supposed to have been attached to, if not kept in, the temple of Jerusalem, and the Hebrew authors speak of "the multitude of books;" an expression which seems to imply that the collection was not confined to the sacred books alone, but included others, relating probably to the laws and institutions of Moses, and the history of the Jewish nation. The books, particularly those of history, had indeed become so numerous, that Judas Maccabeus caused extracts to be made and circulated from those contained in the library of Nehemiah,⁴ mentioned in the second book of Esdras, in which also were preserved the writings of the prophets, the compositions of David, the letters of the Hebrew kings, and the records of offerings. We know nothing of early Jewish literature beyond the books which are contained in the Old Testament. It has been supposed, however, that they had some cities celebrated on account of the sciences which were there cultivated. Amongst these may be mentioned the town called by Joshua *Kirjath-sepher*, or the *City of the Book*, which was situate near the confines of the tribe of Judah. In later times, the university or school of Tiberias was not less celebrated. It is probable that this and other academies of the same description were furnished with libraries.⁵

Libraries
of the
Persians.

Scripture also mentions a library of the kings of Persia, which some suppose to have consisted of the historians of that nation, and of memoirs on the affairs of state, but which appears rather to have been a depository of the laws, charters, and ordinances of the Persian kings. In the Hebrew text it is stated that a search was made "in the house of the rolls, where the treasures were laid up in Babylon," for a decree issued by Cyrus ordaining a temple to be built at Jerusalem; the ordinance sought for, however, was found, not in Babylon, but at Acmetha, in Media.⁶ It appears that "the house of the rolls" was not a library belonging to the Persians, but a collection of the records or archives

of the kingdom. In the recent discoveries in Assyria, in the palace at Nineveh, a vast collection of clay tablets, inscribed with cuneiform inscriptions was found, forming, as it were, the royal library. The progress made in deciphering the inscriptions, in this cuneiform character, was brought before the meetings of the British Association at Glasgow and at Cherttenham, by Colonel Sir Henry Rawlinson, in two most interesting lectures. This system of cuneiform writing was found to be closely allied to the hieroglyphic expression; and, although many of the rock inscriptions of Persia were trilingual, each of the languages, the Chaldee, Assyrian, and Babylonian, being unknown, it seemed to defy all attempts at translation; yet this has been accomplished by a singular combination of learning and ingenuity. Sir Henry Rawlinson stated that about 20,000 of these tablets, more or less injured by fire, were now brought to England, and are in the British Museum; and that the extensive series, when fully deciphered, would be the means of furnishing most important additions to our knowledge of the ancient world. Of these cuneiform inscriptions, lithographic facsimiles are about to be published by the Trustees of the British Museum; and half of the impression is to be placed at the disposal of Sir Henry Rawlinson, who will, at his own expense, accompany these copies with literal translations, in Latin.

Ancient
Libraries.
Tabular
libraries
of the
Assyrians.

Very recently, M. Jules Oppert (to whom has been entrusted by the French government the mission of examining and reporting on the acquisitions for which the British public are mainly indebted to the research and energy of Mr Layard) has copied a considerable series of these inscribed tablets, and has expressed his conviction that there is a large class of them to which, in a special and unique sense, the designation of a "public library in clay" is applicable. These he believes to have been prepared by command of Sardanapalus V. (about B.C. 650), expressly for purposes of public instruction; and he quotes a remarkable inscription to this effect: "Palace of Sardanapalus, king of the world, king of Assyria, to whom the god Nebo and the goddess Ourmit have given ears to hear and eyes to see what is the foundation of government. They have revealed to the kings my predecessors this cuneiform writing. The manifestation of the god Nebo . . . of the god of supreme intellect,—I have written it upon tablets,—I have signed it,—I have put it in order,—I have placed it in the midst of my palace for the instruction of my subjects."⁷

Amongst the Greeks, as amongst other nations, the first Libraries consisted merely of archives, deposited, for the sake of the preservation, in the temples of the gods. The sacred books, of which mention is made by Dionysius of Halicarnassus, under the denomination of *Deltids*, were of this description.

It has been often said that Pisistratus the tyrant was the first who established a public library in Athens; but the statement rests mainly on the testimony of Aulus Gellius, who wrote about seven hundred years after the time of Pisistratus. In this alleged library, the founder is said to have deposited the works of Homer, which he had collected with great difficulty, and at a very considerable expense; and the Athenians themselves were at great pains to increase the collection. The reputed fortunes of this library were various and singular, if true. It was transported to Persia by Xerxes; brought back by Seleucus Nicator; plundered by Sylla; and at last restored by the Emperor Hadrian. The entire story,

Ancient
Libraries.

however, is a conjectural one. That Pisistratus was a promoter of learning, and that he rendered eminent service by his Homeric researches, is incontestible. But that he formed anything which even remotely resembled a library, in the ordinary meaning of the term, is an assertion unsupported by adequate evidence; and just as little foundation is there for the romantic vicissitudes which complete the tale. Nor is there much better authority for the statement, that when, on the invasion of the Roman empire by the Goths (A.D. 260), Greece was ravaged, and in the sack of Athens they had collected all the libraries, and were upon the point of setting fire to this funeral pile of ancient learning, one of their chiefs interposing, dissuaded them from the design, observing at the same time, that as long as the Greeks were addicted to the study of books, they would never apply themselves to that of arms.

Strabo has stated that Aristotle was the first known collector of a library, and that to him was also due the honour of having suggested to the Ptolemies the formation of that great collection, which was scarcely more the wonder of antiquity than it has been the conundrum of modern scholarship. Aristotle bequeathed his library, with many of his own writings, to Theophrastus, who appears to have made considerable additions to it, and who, in his turn, bequeathed it to Neleus. The latter, according to Strabo, carried the collection to Scepsis in the Troad, where it subsequently fell into disorder, and was at length concealed in a cave, that it might escape the eager researches of the kings of Pergamus. "At length," continues Strabo, "but not before the books had been injured by damp and worms, they were sold to Apellicon of Teos,—rather a collector than a philosopher (*φιλόβιβλος μάλλον ἢ φιλόσοφος*),—who, by unskilful attempts at the restoration of defective and mutilated passages in the writings of Aristotle, increased the injury by corrupting the text."¹ On the capture of Athens by Sylla, the Library of Apellicon—not that of Pisistratus—was seized by the conqueror and carried to Rome.

But Strabo's account of the matter—on which mainly was founded the absurd story so long current as to the loss for several generations of the Aristotelian writings—is entirely at variance with that given by the epitomist of Athenæus, according to whom the Library of Neleus had long before been bought by Ptolemy Philadelphus and transferred to Alexandria, "with all those which he had collected at Athens and at Rhodes."² This statement accords better with the known existence and publicity of Aristotle's works, but has its own difficulties. It is, however, at least matter of reasonable probability that, from whatever cause, part of the collection went to Alexandria, and part remained at Scepsis. From the rivalry of the Attalic kings with the Ptolemies, it may well have resulted that the fame of the acquisition for Alexandria of part of the library of Aristotle, may have given a keener edge to their covetousness of what remained.

Library of
Pergamus.

Next to the Alexandrian Library, that of Pergamus was the most conspicuous, and, according to Plutarch, contained 200,000 volumes. It was founded and successively enriched by the kings of Pergamus, all of whom were zealous promoters of the arts, and to one of whom we are indebted for the invention of parchment (*Charta Pergamena*). Attalus surpassed all his predecessors in magnificence, and after their example devoted part of his treasures to the purchase of the principal works or writings of his age. As already noticed, the Pergamean Library was presented by

Antony to Cleopatra, in order to form the foundation of a new library at Alexandria. Vitruvius makes honourable mention of both these libraries.³

Ancient
Libraries.

These particulars, scanty as they may no doubt seem, are nevertheless sufficient to show that the libraries of Greece, in ancient times, were both numerous and extensive. But a question of much more immediate interest here presents itself, viz., whether any of the treasures which they were enriched still remain undiscovered, and where these may be supposed most likely to be found. On this subject various conjectures have been formed, particularly in regard to the remains of the ancient Greek historians. It is well known that many manuscripts had been collected at a vast expense in Greece for the Library of Buda, which was destroyed by the Turks in the year 1526. In this library Alexander Brassicanus had seen the whole of the *Hyperides* with *scholia*, the works of many of the Greek fathers, and also those of classical writers. From it issued parts of Polybius and of Diodorus Siculus. A manuscript of Heliodorus, from which was afterwards printed the first edition of the *Æthiopica*, likewise belonged to it, having been found by a soldier, who carried it to Vincentius Obsopæus. Neander, speaking of this collection, says, "Ex media Græcia inæstimandis sumptibus emerat Matthias Corvinus rex."⁴

Constantinople and Athos have contributed the greater number of the ancient manuscripts which are still extant in different parts of Europe. Until a comparatively recent period there were monasteries full of learned men at Byzantium, and every monastery had its library. The Turks, on their conquest of Constantinople, did not indulge in that indiscriminate destruction which has sometimes been imputed to them. Mohammed II. secured the library of the Greek emperors, which his successors preserved until it was destroyed by Amurath IV. At Byzantium, Constantine Lascaris transcribed many of the works which were afterwards conveyed to the Royal Library at Madrid; and in this city were procured those manuscripts which, having been presented to Hurtado de Mendoza by Solymán II., were left by the former to the Library of the Escorial. Possevin has given partial catalogues of some of the libraries at Constantinople; and an early traveller, who visited that city in the year 1597, mentions a valuable collection which he had seen there, though without specifying its contents. With respect to Athos, it appears that there were deposited in one library alone 200 manuscripts, originally obtained from the monasteries upon the mountain; and a great part of those formerly at Moscow had been collected by the monk Arsenius, in Athos, at the suggestion of the patriarch Nikon. Thessaly, Chios, Corfu, Crete, Cyprus, Chalcæ, Rhodes, and Epidauria, may also be mentioned as places which, at different times, have supplied manuscripts.

Mr Walpole long since expressed the opinion, that notwithstanding the acquisitions which have already been made, researches in the Levant should not be intermitted. By these many manuscripts may still, according to him, be rescued from destruction.⁵ No care whatever appears to have been taken to preserve them. Dr Covel mentions having seen, in the monasteries of Mount Athos and elsewhere, vast heaps of manuscripts of the Fathers, and other learned authors, all covered over with dust and dirt, many of them rotten and spoiled, and never in any instance placed upon shelves or arranged in good order.⁷ A list of the theological manuscripts in the Library of Patmos has been

Researches
for ancient
Greek MSS.

given by Possevin; and another, copied by the Marquis of Sligo, has been published by Mr Walpole. The actual catalogue contains the titles of 92 manuscripts, and about 400 printed volumes; but the Greek compiler has not stated any circumstance relating to the manuscripts by which an estimate of their value may be formed. He gives no information concerning the form of the letters or that of the manuscripts, or upon any of those subjects by which a knowledge of their respective dates might be obtained. But there is one manuscript mentioned in the catalogue, in regard to which it is impossible not to feel more than ordinary curiosity. We allude to a manuscript of Diodorus Siculus, an accurate inspection of which would probably determine whether the hopes which were oftener than once entertained, of recovering the lost books of that historian, were in this instance also to be disappointed.¹ But, without dwelling longer upon particulars, we may observe, that notwithstanding the sanguine expectations entertained by the admirers of ancient learning, very few valuable manuscripts have latterly been discovered; and, with the exception of the fragments of ancient authors, deciphered from palimpsest, or rescribed manuscripts, it must be admitted, that those accidentally rescued from destruction have, in general, been either of comparatively modern date or of but little consequence. Neither the inquiries which have been extended to the African states, nor the excavations and researches made at Herculaneum and Pompeii, have recovered the lost historians, or indeed brought to light any works of importance.² (See HERCULANEUM.)

The Hon. Robert Curzon, in the charming volume which describes his *Visits to the Monasteries in the Levant*, records his success in Abyssinia, Turkey, and Greece, in obtaining a number of very early and important MSS. A portion of these MSS. are described in a *Catalogue of Materials for Writing; Eastern Writings on Tablets and Stones, Rolled and other Manuscripts, and Oriental Manuscript Books, in the Library of the Honourable Robert Curzon, at Parham, in the County of Sussex* (London, 1849, folio). Of this volume, which contains various interesting facsimiles, only 50 copies were printed. From information communicated by Mr Curzon as to the existence of ancient Greek scrolls in the monasteries of the East, the Rev. H. O. Coxe has recently (1856) obtained leave of absence from the Bodleian Library, at the request of government, to proceed to the Levant, in search of such MSS.; and a more competent scholar for such an object could not have been found.

The French government has also turned its attention towards the same object, and has entrusted a similar mission to M. Lebarbier, a young but already distinguished student of the *École Française d'Athènes*. In August 1856, M. Guignaut, in the name of a committee appointed to examine the works and proceedings of this school at Athens, read a report to the Academy of Inscriptions, in which the first fruits of M. Lebarbier's labours are described, with more especial reference to a library designated by M. Guignaut the "Library of the Holy Sepulchre at Constantinople." After stating that the library possesses a considerable number of MSS., M. Guignaut proceeds: "But, unfortunately, these MSS. comprise little besides homilies, prayers, theological and controversial treatises (written at periods not very remote from our own), translations from Latin or Italian into modern Greek, . . . and works of like kind. The ancient authors, all long since published, are for the most part modern transcripts." . . . "But," adds the learned reporter, "if the Library of the Holy Sepulchre

offers little aid to classical literature, it is rich in documents which throw new light on the history of the Greeks after the fall of the Byzantine empire."³ Thus far, it must be admitted, these renewed researches do not present a very promising aspect as regards that particular department of literature with which alone we have here to do. But the field is one in which the discoveries of an hour may possibly present rich compensation for the toil of years.

Rome was still in its infancy when the archives of the Etruscans contained a continuous collection of public acts, and particularly an uninterrupted series of births and deaths, that enabled that people to fix the unequal duration of the eight centuries of their previous history, which they reckoned up to about the middle of the sixth century before Christ. The details given by Censorinus in Varro, prove that the Etruscans kept regular registers of births and deaths, from the epoch of their first establishment in Italy, which Larcher refers to the year 1844 before Christ; that, the eighth century thereafter, to which the Etruscan histories were written, must have been the sixth before the Christian era, in which other histories appeared that are no longer extant, and that, during these eight hundred years, the most extended term of human life was nearly the same as at the present day. In the works of Dionysius of Halicarnassus, of Plutarch, and other ancient authors, we also discover scattered glimpses of the history of Italy in the most remote times, and learn that the tribes or races by whom the Etruscans were surrounded had also their historical archives. It may even be supposed that the Romans, in causing their Capitoline marbles to be engraved, followed, amongst others, the example of Præneste, a city much more ancient than Rome, and which had long continued the practice of classifying, as well as engraving its municipal records. Such were the sources consulted by several historians who treated of the antiquities of different Italian nations, particularly Zepodotus of Trezene, who composed a history of the Ombrians.

If the ancient Greeks had but few books, the ancient Romans possessed still fewer. Incessantly occupied in military expeditions, defensive wars, and the aggrandizement of their empire, that warlike people had no leisure, and, probably, as little inclination, to cultivate letters. It was not until they had subdued Magna Græcia that they began to emerge out of barbarism, nor until they had accomplished the conquest of Greece itself, that a taste for arts, sciences, and books was diffused amongst them. They became civilized by frequent contact and familiarity with civilization. The immediate consequence of the conquest of Greece was a more frequent intercourse with the Greeks, at once their subjects and their masters; and in proportion as they became acquainted with the literature and arts of that refined people, the asperity of character and manners which had distinguished this nation of conquerors began to disappear.

The first library established at Rome was probably that founded by Paulus Æmilius, B.C. 167. Having subdued Perses, King of Macedonia, he enriched the city of Rome with the library of this conquered monarch, which was subsequently augmented by Sylla.⁴ On his return from Asia, where he had successfully terminated the first war against Mithridates, Sylla visited Athens, whence he took with him that Library of Apellicon the Teian, which has been mentioned already. Lucullus, another conqueror of Mithridates, was not less distinguished by his taste for books. The number of volumes in his library was immense; and they

⁴ Such is the statement of Isidorus (*Origines*, l. vi., c. 4), though Plutarch (*in Vit. Æmil.*, tom. ii., p. 180, ed. Bryan) expressly says that he reserved for his sons, who were lettered men, the books taken from the library of King Perses.

Ancient
libraries.

were written in the most distinct and elegant manner possible. But the use which he made of his collection was still more honourable to that princely Roman than the acquisition or possession of it. His library was open to all; and the Greeks, who visited Rome, resorted to the galleries and porticos of Lucullus as to the retreat of the Muses, where they spent whole days in conversation on literary subjects. But although both Sylla and Lucullus liberally gave public access to their literary treasures, still their libraries can, in strictness, be considered as only *private* collections. Amongst the various projects which Julius Cæsar had formed for the embellishment of Rome was that of a *public* library, which should contain the largest possible collection of Greek and Latin works; and he had assigned to Varro the duty of selecting and arranging them; but it has been supposed that this design was frustrated by the assassination of the dictator; and that the establishment of public libraries did not take place until the reign of Augustus.

The honour of suggesting these valuable institutions is ascribed by the elder Pliny¹ to Asinius Pollio, who erected a public library in the atrium of the temple of Liberty, on Mount Aventine Hill. This library, it is added, was formed *ex manubiis*, and in it was placed a bust of Varro. It would seem probable, from the latter circumstance, that Varro after all may have carried out the plan entrusted to him by Cæsar, and that Pollio may have merely enlarged the library thus begun. The exploits that were most likely to have yielded him the spoils of war, were of a date long subsequent to that of Cæsar's commission to Varro.² Augustus, amongst other embellishments which he bestowed upon Rome, erected two public libraries, viz., the Octavian and the Palatine. The Octavian Library, which was thus denominated in honour of the emperor's sister, stood in the portico of Octavia; and the charge of it was committed to Melissus, who had been manumitted by Augustus. The Palatine Library was added by Augustus to the temple of Apollo, which he had erected on the site of that part of the Palatine House which had been struck by lightning. There were deposited the corrected books of the Sybils; and, from two ancient inscriptions quoted by Lipsius and Pitiscus, it would seem that it consisted of two distinct collections, one Greek and the other Latin. This library having survived the various revolutions of the Roman empire, existed until the time of Gregory the Great, whose mistaken zeal led him to order all the writings of the ancients to be destroyed.³ The successors of Augustus, though they did not equally encourage learning, were not altogether neglectful of its interests. Suetonius informs us that Tiberius founded a library in the new temple of Apollo; and we learn from some incidental notices, that he instituted another in his own house, called the Tiberian Library. Vespasian, following the example of his predecessors, established a library in the temple of Peace, which he erected after the burning of the city by order of Nero; and even Domitian, in the commencement of his reign, restored at great expense the libraries which had been destroyed by the conflagration, collecting copies of books from every quarter, and sending persons to Alexandria to transcribe volumes in that celebrated collection, or to correct copies which had been made elsewhere. Various writers have asserted that there was a library attached to the Temple of the Capitol; but they have not informed

Ancient
libraries.

us by whom it was founded. Lipsius ascribes it to Domitian; whilst Donatus refers it to the Emperor Hadrian, by whom it was at least enlarged, if not founded, and who probably erected the Tiburtine Library, at Tibur, in the vicinity of Rome.⁴ But the most magnificent of all the libraries founded by the sovereigns of imperial Rome was that of the Emperor Ulpian Trajanus, from whom it was denominated the Ulpian Library. It was erected in Trajan's Forum, but afterwards removed to the Viminal Hill, to ornament the baths of Diocletian. In this library were deposited the elephantine books, written upon tablets of ivory, wherein were recorded the transactions of the emperors, the proceedings of the senate and Roman magistrates, and the affairs of the provinces. It has been conjectured that the Ulpian Library consisted both of Greek and Latin works; and some authors affirm that Trajan commanded all the books which could be found in the cities he had conquered to be immediately conveyed to Rome, in order to increase his collection. The library of Domitian having been consumed by lightning, in the reign of Commodus, was not restored until the time of Gordian, who rebuilt the edifice, and founded a new library, adding thereto the collection of books bequeathed to him by Quintus Serenus Samonicus, the physician, amounting, it is said, to no less than 72,000 volumes. Donatus conjectures that this library was deposited in the palace of Pompey.⁵

In addition to the imperial libraries, there were others Libraries to which the public had access in the principal cities and in the colonies of the empire. Pliny mentions a public library provinces. which he had founded for the use of his countrymen; and Vopiscus informs us that the Emperor Tacitus caused the historical writings of his illustrious namesake to be deposited in the libraries. But the irruptions of the barbarians who overran and desolated the western empire proved more destructive to the interests of literature than either volcanoes or earthquakes, and soon caused the disappearance of those libraries which, during several centuries, had been multiplied in Italy.

When Constantine the Great (A.D. 336) made Byzantium the seat of his empire, decorated that city with splendid edifices, and called it after his own name; desirous to make reparation to the Christians for the injuries they had suffered during the reign of his predecessor, he commanded the most diligent search to be made after those books which Diocletian had doomed to destruction; he caused transcripts to be made of such as had escaped the fury of the Pagan persecutor; and, having collected others from various quarters, he formed the whole into a library at Constantinople. On the death of Constantine, however, the number of books in the imperial library was only 6900; but it was successively enlarged by the Emperors Julian and Theodosius the younger, who augmented it to 120,000 volumes. Of these, more than half were burned, in the seventh century, by the command of the Emperor Leo III., who thus sought to destroy all the monuments that might impede his opposition to the worship of images. In this library was deposited the only authentic copy of the Council of Nice; and it is also said to have contained the poems of Homer, written in gold letters, together with a magnificent copy of the Four Gospels, bound in plates of gold, enriched with precious stones; all of which were consumed in the conflagration. The convulsions which distracted the lower empire were by no means favour-

dle ages.

able to the interests of literature. In the eleventh century learning flourished for a short time during the reign of Constantine Porphyrogenetus; and this emperor is said to have employed many learned Greeks in collecting books, and forming a library, the arrangement of which he himself superintended. But the final subversion of the Eastern Empire, and the capture of Constantinople in 1453, dispersed the learned men of Greece over Western Europe, and placed the literary remains of that capital at the mercy of the conqueror. The imperial library, however, was preserved by the express command of Mohammed, and continued, it is said, to be kept in some apartments of the seraglio; but whether it was sacrificed in a fit of devotion by Amurath IV., as is commonly supposed, or whether it was suffered to fall into decay from ignorance and neglect, it has been repeatedly asserted that the library of the Sultan contains only Turkish and Arabic writings, and not one Greek or Latin manuscript of any importance. The opinions of competent scholars continue, nevertheless, to be divided on this point. Even in Germany, where the expectation of important accessions from this quarter has confessedly declined, we find an authority so eminent on such questions as that of Tischendorff still on the side of the old belief. He thinks it probable, he says (writing in 1845), "that the seraglio of the Sultan conceals ancient and valuable MSS., though complete obscurity prevails as to their contents;" and he proceeds to ask who in our day would have credited the existence of "walled-up" libraries, yet a walled-up library was very lately one of the mysteries of Cairo.¹

Upon the whole, it appears that books were abundant, both at Rome and at Constantinople, and that learned men in those cities had at their command greater resources than might at first be supposed. Some idea of the quantity of books accessible to persons of study and research may be formed from the great number of references and citations to be found in the works of some authors, particularly in those of Strabo, Pliny, and some others. It is, however, to be remembered, while referring to the large number of books said to have been contained in these ancient libraries, that a very erroneous impression would be made were they to be reckoned according to modern computation. Each work being written on separate rolls, the number would necessarily be greatly increased, when the books of Livy or Pliny were each reckoned as a distinct roll, or volume; and Balbi (*Essai Statistique*, &c., p. 82, Vienna, 1835, 8vo.) further suggests the comparison that these rolls of the ancients might be reckoned as so many parts of books, published by subscription, or of periodicals. According to this view, the largest libraries in ancient times might be represented by the contents of a modern library containing from 50,000 to 100,000 volumes.

II.—LIBRARIES OF THE MIDDLE AGES.

General
remarks.

General epithets and figurative expressions frequently convey a meaning which is calculated to mislead. Hearing constantly of "the dark ages," "the period of intellectual night," and "the season of winter in the history of man," we are apt to imagine that, during the time thus designated, the human mind was utterly palsied, and all learning extinct. But in fact, throughout that period, reason, though misdirected, was not asleep; philosophy was rather bewildered than inert; and learning was immured, but not lost. In no part of that long period which extends from the reign of the Emperor Justinian, when Greek and Roman literature everywhere lay open to the light of day, to the fall of Constantinople and the revival of learning in the fifteenth century, do we entirely lose the traces even

of the classic authors, much less of sacred literature; for in each intervening age, and in every quarter of Europe, there were writers whose works, being still extant, afford abundant evidence of their acquaintance with most of the principal authors of more remote times.² When the empire of the west sunk under the overwhelming pressure of barbarian invasion, those institutions which had been founded and nurtured in the midst of civilization, were, no doubt, swept away by the torrent which desolated Italy, and spread its ravages over all parts of the empire. But learning, though expelled from her ancient establishments, and forced from her favourite haunts, found an occasional asylum in the monasteries, which, amidst all the violence and anarchy that reigned without, were sometimes permitted to remain in undisturbed tranquillity, respected even by the barbarians who had overthrown an empire.

Libraries
of the mid-
dle ages.

It is doubtless true that comparatively little is recorded of the libraries of those ages which intervened between the fall of the Roman empire and the revival of letters in Europe, about the middle of the fifteenth century. But, every age produced learned and inquisitive men, by whom books were highly prized, and industriously collected. Cassiodorus, minister of Theodore, King of the Goths, retired to a monastery which he had built, and there founded a library for the use of the monks, about the middle of the sixth century. At a later period, Charlemagne, distinguished as a patron of learning, instituted, near Lyons, a library, which, according to the statements of historians, contained many books bound in a magnificent manner.

That on the general merits of the monastic institute the most conflicting opinions should still extensively prevail, cannot be matter of legitimate surprise, if we call to mind that monasticism played a great part in the world for a thousand years; and that during that long period the most incongruous views as to what a monk ought rightly to be in, and to do were current even within the walls of monastic communities. But this diversity of opinion extends also to that more limited phase of cloister life which has relation to literature. Whilst some writers contend that but for monks ancient learning would have wholly perished, others have gone the length of asserting that in monks literature has always had its worst enemies.

Monasteries; system of transcription pursued there-in.

To arrive at any useful conclusion on such a question, it must be remembered that at no time and in no country was literature in any of its forms the main object of monastic life. In the earlier ages, when the embers of Paganism were still smouldering, the preservation of Pagan poetry would have seemed a strange employment for the confessors and missionaries of Christianity. The labours of the Scriptorium originated not so much in the love of letters as in the love of souls. As the monk became less of a mere ascetic, and aspired to become a civilizer, he necessarily began to be a collector of books, and then their author or their transcriber. But, for a long time, the books that he gathered, and those that he composed, were in the main either theological or ethical. Here and there, however, individual minds of special energy grew large enough to perceive classical beauty without relaxing their grasp of such Christian truth as they had, and became the venerated masters of numerous disciples. If monastic literature reflects but too much of the corruption of mediæval Christianity, it remains still undeniable that from Bibles transcribed by monkish hands, and from the best of the productions of the fathers of the church, preserved in monkish libraries, the men who successively wrestled with that corruption, and were the instruments by which Christianity was kept alive, drew their inspiration and their solace; and that very corruption, in some of its results, as, for example, in the re-

Libraries
of the mid-
dle ages.

ligious use of a dead language, contributed to the preservation of ancient learning.

At almost all periods of its history the order of St Benedict stands foremost amongst the cultivators of learning and of the arts. Yet whilst the rule of the founder contains much about visiting the sick, relieving the poor, and keeping the body in subjection, it contains very little indeed about books. Nor is there much more about them in the various constitutions of the successive "Reformers" of the order. But no order was so fortunate in the possession of a long line of men remarkable for mental vigour and force of character. If the early Benedictines are less conspicuous at periods of comparative enlightenment than at periods when all around them was gloomy, they were unquestionably the first pioneers and builders up of European civilization, and they laid its foundations broad and deep enough to resist the attacks of their own unworthy successors. They never sank so low as did most other orders of monks; and at a long subsequent period, in producing the illustrious congregation of St Maur, a service was rendered to learning—in the special sense of that term—which neither has, nor is likely to have, any parallel in monastic history.

Monte Cassino has been called the Sinai of the middle ages. It was certainly the cradle of a series of communities which spread all over Europe, and of which not the least famous were our British monasteries, such as Yarrow, Wearmouth, Bury St Edmunds, Croyland, Whitby, Reading, St Albans, all of which were distinguished for the pains taken in them about the collection and transcription of books. This system of transcription, to which alone we are indebted for all that remains of ancient learning, was carried on to an extent, of which those who are unacquainted with the history of the middle ages can form no conception. We have already had occasion to advert to the occupation of the inmates of the monastic establishments on Mount Athos, the lofty promontory which stretches from the Macedonian coast far into the Ægean Sea; and we have also noticed the immense number of manuscripts which have at different times issued from these establishments. Many manuscripts still extant prove that the copying of books was likewise practised to a great extent during the middle ages, in the monasteries of the Morea, and in those of Eubœa (Negropont), and of Crete (Candia). The latter island seems, indeed, to have been a place of refuge for learned men during the disastrous period which preceded the fall of the Eastern Empire; in its monasteries they found an asylum and the means of subsistence. In Calabria and the kingdom of Naples, fifty religious establishments have been mentioned, from which proceeded a large number of the books afterwards collected in the libraries of Rome, Florence, Venice, and Milan.¹ In the monasteries of Western Europe, also, the same system of transcription was carried on. It is mainly to the labours of these establishments, that we are indebted for the remains of the classic authors, and the preservation of the sacred books, which they so carefully transcribed.

This statement needs no better illustration, or more conclusive proof, than would be furnished by a digest of some of the more important of those catalogues of monastic libraries which have come down to us in no inconsiderable number. But however compressed, it would still be impracticable to supply in this article even the briefest abstract of such a summary. We can only indicate to the reader who may desire to pursue the subject some of the sources of information to which he may resort. And this purpose will probably be better attained by directing him to books in which specimens of such catalogues have been printed, than by any enumeration of those which exist in manu-

script, very curious as are some which remain as yet unpublished.

A catalogue of the library of the famous Benedictine Abbey of Corbey was first printed by Sir Thomas Phillipps, and has been reprinted in the Leipzig journal *Serapeum* for 1841. In later volumes of that periodical will also be found a curious series of ancient catalogues of that of Klosterneuburg (a library which still exists, and in recent days has been magnificently lodged); of Saint Vaast of Arras, and of some other monasteries of minor fame; together with many historical notices of monastic libraries (the full catalogues of which are no longer extant), chiefly from the pen of the accomplished and laborious bibliographer Mr E. G. Vogel of Dresden. An interesting series of catalogues of the books of the great monastery of Durham was edited by Mr Beriah Botfield for the Surtees Society in 1838. The catalogue of the library of the Benedictines at Whitby is printed in the Appendix to Mr Young's *History* of that town, as is the Peterborough catalogue in Gunton's *History of Peterborough*, and that of Glastonbury in Hearne's *Appendix to the Chronicle of John of Glastonbury*. Of the Abbey of Bec, M. Felix Ravaisson published an early catalogue in his *Rapports au Ministre de l'Instruction Publique sur les Bibliothèques des départements de l'Ouest* (1841). Not less interesting, although far more concise than most of these, is that metrical catalogue by Alcuin of the treasures of the Augustinian monastery at York, which Mabillon communicated to Dr Gale for publication in his *Scriptores Rerum Britannicarum*.

The reader who may refer to the texts of some of these catalogues, or who may turn to the many extracts from similar documents which are to be found in the *Spicilegium* of D'Achery, the *Thesaurus Anecdotorum* of Martene, Durand, and Pez, and in the narratives of the literary travels of these and of other Benedictines of St Maur, will perceive that monastic collections were often of no small extent, and of not inconsiderable diversity; nor will he feel much difficulty in admitting that but for monks the dark ages must have been dark indeed.

The revival of learning is usually reckoned to have commenced in the fifteenth century; but even in the fourteenth century. Fourteenth century. a decided advancement in almost every department of literature is discernible. Gross and degrading ignorance was wearing away from the bulk of the community in several parts of Europe; the educated classes were acquiring a better taste and more expanded views; and a general awakening of the energies of the human mind was perceptible. This needs no other evidence than is afforded by the works of Dante, Petrarch, Boccaccio, Chaucer, and Gower, which were not merely produced in that period, but extensively read and admired. During no part of that long tract of time which extends from the decline of learning in the sixth century till its revival in the fifteenth, had there been a total extinction of the knowledge of ancient literature; and those inestimable treasures which the religious houses had saved from the ravages of revolution, anarchy, and barbarism, now began to be drawn forth and studied. The continuance of the Eastern Empire till the middle of the fifteenth century, afforded an uninterrupted protection to Greek learning during those periods when Western Europe was laid waste by the Gothic nations; and hence, on the revival of letters, the study of the Greek authors first engaged the attention of those individuals whom an awakening impulse now directed to the cultivation of learning. But that of the kindred authors of Rome soon followed; and the monuments of ancient wisdom and genius which had been preserved in the monasteries, furnished ample materials for laying the foundations of a new and more extensive, if not more perfect, edifice of civilization.

Revival of
learning.

First for-
mation of
modern
libraries.

Invention
of print-
ing.

More than half a century before the taking of Constantinople by the Turks, the learned men of the imperial city, apprehending the approaching ruin of the empire, began to emigrate into Italy. There they opened schools, and became the preceptors of princes, as well as the guides of the public taste, which they directed towards the study of the classical writers of Greece and Rome. The fall of Constantinople, in 1453, filled the Italian cities with these learned strangers. At this period the Italians required only to receive some kind of direction, and to be provided with the means of study. They had for some time been placed in those peculiar circumstances which have almost always proved favourable to the advancement of the human mind. A number of independent states were crowded upon a narrow space, throughout which the same language, diversified by dialects, prevailed, exhibiting, in a sort of reflected or secondary form, that of ancient Italy; whilst the formation of libraries, suggested or favoured by the importation of manuscripts from Constantinople, proved the means not only of making more widely known the works of the Greek authors (which had never fallen into oblivion), but of prompting those researches which issued in the recovery of the Latin writers, many of whom had long been forgotten. The appetite for books being thus revived and quickened, neither labour nor expense was spared in accumulating them; learned men were despatched in all directions throughout Europe, Western Asia, and Africa, to collect manuscripts; and, in the course of a few years, most of the authors now known were brought together in the libraries of Rome, Naples, Venice, Florence, Vienna, and Paris. Aided by the munificence of princes and popes, the scholars of the fifteenth century applied themselves to the discovery, restoration, and publication of the remains of Greek and Roman literature; and, in the course of sixty or eighty years, most of the works now known were committed to the press. Since that time additional discoveries have been made; but the principal improvements of a subsequent date have consisted in the emendation of the text of ancient authors, partly by a more extensive collation of manuscripts than the first editors possessed the means of instituting, and partly also by the lights and aids of a cautious and judicious criticism.¹

The invention of printing, by virtually exempting books from the operation of the law which subjects all human things to decay, has also greatly promoted the process of their renovation. By giving to the issue of an edition of a standard work a degree of importance several hundred times greater than that which belonged to the transcription of a single copy, it has called for a proportionally larger amount of learning, diligence, and caution, in the work of revision; and, by enabling each successive editor to avail himself of the labours of his predecessors, all the advantages resulting from the concentration of many minds upon the same subject have further been secured. Since the fifteenth century, therefore, the lapse of time, instead of gradually impairing and corrupting the literary remains of antiquity, has incessantly contributed to their renovation; what was then unknown or doubtful, imperfect or corrupted, has been ascertained, restored, and completed; and the learning and industry of the four centuries which have since elapsed, being constantly directed towards the same objects, have left comparatively few questions of literary antiquity open to controversy.

Libraries
of the mid-
dle ages.

Several of the great libraries of Europe date their first beginnings during the hundred years between 1365, when Charles V. of France had already won renown as a collector of choice manuscripts, and 1463, when the art of printing had established itself, without having as yet materially interrupted the labours of the copyists. Within this period are included the foundation of the Imperial Libraries of Paris and of Vienna, of the Laurentian Library at Florence, and of the Library of the Vatican; and the liberal gifts of books which were made by Sir Richard Whittington to the Franciscans of London; by Humphrey, Duke of Gloucester, to the University of Oxford; by King Henry VI. to All Souls College; and by Niccolò Niccoli to his fellow-citizens of Florence. It also witnessed the commencement of those splendid collections of Frederick, Duke of Urbino, and of Matthias Corvinus, King of Hungary, which eclipsed all preceding libraries, and were counted amongst the marvels of the age. But, unfortunately, whilst the Urbino Library has escaped the almost total destruction which befel that of Corvinus, it has lost much of its value by division. Its manuscripts are still conspicuous amongst the treasures of the Vatican, but they are less accessible to students than they were in the romantic seat of the old dukes; and the printed books are scattered, some being at Castel Durante, others in the Library of the "Sapienza" at Rome, and others, again, still remaining at Urbino.²

Within the same period, too, is comprised the foundation of the oldest of those town libraries in which Germany has become rich. As early as 1413, Andreas von Slomnow established a library at Dantzic in connection with the church of St Mary.³ His example was followed by Conrad von Hildesheim at Ratisbon in 1430;⁴ by Heinrich Neidhart at Ulm in 1440;⁵ and by Conrad Kühnhofer at Nuremberg in 1445.⁶ Nor was France far behind in a similar foundation, although in that country the first step was not followed up with equal vigour. There is an account of the purchase of books for a public library by the Common Council of Aix in the year 1419.⁷ For any such record, or for any entry at all respecting such an institution, in the proceedings of an English municipality, it will, we fear, be necessary to descend almost two centuries. The striking contrast which for many generations existed between Great Britain and some of the continental states, as respects the possession of libraries publicly accessible, was none the less, but rather the more, deplorable for the fact that in earlier days it had been, as there is good hope that in future days it will yet be, quite otherwise. In that first "revival of letters" for which the Europe of the middle ages was so greatly indebted to the genius and energy of Charlemagne, we find Alcuin writing to his imperial patron, that nothing so wrought within him a longing to return to England as the memory of the books which there had abounded, and of which in France there were so few. He repeatedly urges the Emperor to send messengers to England for manuscripts. So highly were those prized which he had himself brought with him to the court, that they became the foundation of a special school of scribes and illuminators in the country round Aix-la-Chapelle, which for many ages, it is said, remained faithful to Saxon traditions.

More than five centuries later we find the patron saint of British book-lovers, Richard Aungerville, Bishop of Durham, in the midst of his lamentations at the degeneracy of morals, and at the supremacy of the lust of power and gain

¹ Taylor, *Hist. of the Transm. of Ancient Books*, p. 106. "This restoration," continues Mr Taylor, "of the remains of ancient works to their pristine integrity, has not been effected like that of a dilapidated building or mutilated statue, by the addition of new materials in an imagined conformity with the plan and taste of the original work, but by the industrious collection and replacement of the very particles of which it first consisted."

British
libraries.

over the old love of knowledge, bursting into a cry of triumph at the apparent dawn of a brighter day. He quaintly recalls, indeed, the almost tumultuous pleasure with which, in his youth, he used frequently to visit "Paris, the paradise of the world! . . . where are delightful libraries in cells redolent of aromatics, . . . flourishing green-houses filled with all sorts of volumes, . . ." but thinks there are already indications, that as "the admirable Minerva once deserted Athens, and then retired from Rome, she has, in like manner, given the slip to the Parisians, and has at last happily reached Britain, the most renowned of islands."¹

The good bishop practised what he taught. He is the first recorded donor of books to the University of Oxford. His example was followed by several other prelates and eminent personages; but all these benefactions were destroyed in the stormy days of the Reformation. Perhaps of all the incidental losses that were swallowed up, if we may so speak, in that great gain, there was none more deserving of regret than the loss of a precious opportunity for adding literary to religious reform. Many of those who most hated monkish corruptions have borne striking testimony to the worth of monastic libraries, even after long years of neglect and injury. That stern opponent of the Romanists, Bishop Bale, for example, keenly laments that in "turning over the superstitious monasteries so little respect was had to the libraries, for the safeguard of those noble and precious monuments. . . . Avarice was the . . . dispatcher which made an end both of our libraries and books, unto the no small decay of the commonwealth." And then he adds, in glowing words, that expression of deep regret that so favourable an occasion had not been seized for the establishment of *county libraries* throughout England, to which we have elsewhere adverted, and concludes thus:—"But to destroy all without consideration is, and will be, unto England for ever, a most horrible infamy among the grave seniors of other nations."²

It was not until the reign of James I. that Great Britain could boast even a "Royal Library" worthy of the name. In 1570 Sir Humphrey Gilbert had vainly pressed on the attention of Queen Elizabeth the superior advantages which men of letters enjoyed in other countries, and the national glory which would result from the establishment of a royal academy and library upon an adequate scale. But what the monarch failed to do was in process of time undertaken by some private persons. In 1580 Clement Littill laid the corner-stone of the Library of the University of Edinburgh. In or about 1588, Sir Robert Cotton commenced that noble collection of manuscripts which long afterwards was to become not the least fruitful germ of our National Museum. In 1597 Sir Thomas Bodley resolved (to use his own words) "to take his full farewell of all state employments, . . . and to set up his staff at the library door in Oxon."³ And, in 1601, a most worthy, though unusual, memorial of military gratitude, laid the foundation of the fine Library of Trinity College, Dublin.

Our historical summary of the growth and fortunes of these and of some others of the more conspicuous European libraries must needs be a brief one. We arrange it under the main divisions of (1.) *British*, (2.) *Foreign*, (3.) *American* and *Colonial* collections, and begin with those which are of nearest interest.

(1.) BRITISH LIBRARIES.

Library of
the British
Museum.

The Library of the British Museum, which is now deservedly considered as the great national depository of science, literature, art, and antiquities, has been composed of

British
libraries.

various collections successively obtained, and is not more remarkable for its numerous and valuable manuscript acquisitions than it is for that energy in its recent management, which within a few years has raised the collection of printed books, from a position comparatively mean, to one of—to say the least—substantial equality, with the oldest and most favoured of the great collections of Europe.

The Museum owes its immediate origin to the bequest of Sir Hans Sloane, whose collections were purchased agreeably to the terms proposed, in the name of trustees, for the public use. The department of printed books consisted originally of Sloane's Library, which was increased by other collections, including manuscripts of the highest importance. In 1757, George II., by an instrument under the Great Seal, added the Library of the Kings of England, the printed books of which had been slowly collected from the time of Henry VII., and the manuscripts from a much earlier date, to be afterwards mentioned. This collection was very rich in the prevailing literature of different periods; and it included, amongst others, the Libraries of Archbishop Cranmer, of Henry Prince of Wales, and of Isaac Casaubon. His Majesty annexed to his gift the privilege which the Royal Library had long possessed, of being supplied with a copy of every publication entered at Stationers' Hall. The same department was further enriched, in 1763, by a donation from George III. of an extraordinary collection of pamphlets and periodical papers (published in England between 1640 and 1660, and chiefly illustrative of the civil wars in the time of Charles I.), which had been formed by Geo. Thomason, a royalist bookseller in London. These tracts include a most extensive and singular series of ephemeral productions on various subjects, and amount, in the aggregate, to 2220 volumes, containing about 34,000 separate publications or articles. Many of them are single leaves, or broadsides, with woodcuts and portraits; and their value is enhanced in having the dates of publication written on each, and sometimes their prices. That the old Royal Library, which had been under the charge of some of the most learned men in England, should not have been preserved entire, and kept as a distinct portion of the Museum, is matter of serious regret. But, by ill-advised economy, the books were not even always preserved, but many of them, from time to time, sold as duplicates, notwithstanding the interest attaching to dedication copies to different monarchs, and to the splendid and curious bindings of the time, ornamented with the royal arms and cyphers.

It would be vain to attempt a detailed enumeration of all the additions which have since been made, whether by gift or by purchase. Amongst the smaller acquisitions may be mentioned Dr Thomas Birch's library; two collections of books on musical science from Sir John Hawkins, and one from Dr Charles Burney; Garrick's collection of old English plays; numerous classics from the library of Thomas Tyrwhitt, with his manuscript notes; Sir William Musgrave's collection of biography; a collection of classics, enriched with Dr Bentley's manuscript notes; a library of ceremonials, processions, and heraldry, from Mrs Sophia Sarah Banks; and a collection of Italian history and topography, from Sir Richard Colt Hoare. Amongst the larger and more important are, the general library collected by the Rev. Clayton Mordaunt Cracherode, consisting of books of great rarity, and in the finest condition; the law library of Mr Francis Hargrave; the library of science which belonged to the Baron von Moll of Munich; the libraries of M. Ginguené, author of the *Histoire Littéraire d'Italie*, and of the Rev. Dr Charles Burney; and Sir Joseph Banks's library of natural history. Four separate collections of tracts, illustrative of the revolutionary history

British
libraries.

of France, have been purchased at different times by the trustees, in the exercise of the powers with which they are invested. One of these is the collection formed by the last president of the parliament of Brittany, at the commencement of the revolution; two others extend generally throughout the whole revolutionary period; and the fourth consists of a collection of tracts published during the reign of the Hundred Days in 1815; forming altogether a body of materials for the history of the revolution as complete in regard to France, as the collection of pamphlets and tracts already mentioned is with respect to that of the civil wars of England in the time of Charles I. Another feature of the Museum Library is its progressive collection of newspapers from the first appearance of these publications, early in the seventeenth century.¹ Sir Hans Sloane had formed a great collection for his day. But to this was added, in 1818, the Burney collection, purchased at the estimated value of L.1000; and, during a long time past, the Commissioners of Stamps have continued periodically to forward to the Museum copies of all newspapers deposited by the publishers in their office.

King's
collection.

In 1823 the Royal Library collected by George III. was presented to the British nation by his successor, George IV., and ordered by parliament to be added to the library of the British Museum, but to be kept for ever separate from the other books in that institution.² The general plan of its formation appears to have been determined on by George III. soon after his accession to the throne; and the first extensive purchase made for it was that of the library of Mr Joseph Smith, British consul at Venice, in 1762, for which his Majesty paid about L.10,000. In this purchase was included the chief portion of a very extensive and valuable series of drawings and engravings, to be afterwards mentioned, which formed a separate and interesting division of the royal library. In 1768, Mr (afterwards Sir Frederick) Barnard, the librarian, was despatched to the Continent by his Majesty; and, as the Jesuits' houses were then being suppressed, and their libraries sold throughout Europe, he was enabled to purchase, upon the most advantageous terms, a great number of valuable books, including some very remarkable rarities in France, in Italy, and in Germany. The entire collection was formed and arranged under the judicious direction of Mr Barnard, assisted by Mr George Nicol, bookseller to his Majesty for upwards of half a century. Many of the rarest books were secured by him for the collection, at the sale of West's, and other libraries. In addition to the purchase of Consul Smith's books, there remained, as the nucleus of the library, those of Charles II., and subsequent monarchs, chiefly presentation and large-paper copies, which were not included in the previous gift of George II. to the Museum. It may also be noticed, as a matter of regret, that a few of the more remarkable volumes were retained by George IV. We know of at least four books that were specially withheld when the library was transferred to the Museum in 1823. One of these is a splendid copy, the finest, perhaps, in existence, of the *Psalterium*, from the press of Fust and Schœffer, in the year 1457, being the earliest book known with a date. It is superbly bound in garter-blue velvet, having on the sides the royal crown and cypher in solid gold, with embossed gold corners and clasps. The second is *The Doctrinal of Sapience*, the only book known to have been printed by Caxton on vellum. A third volume is the *Shakspeare*, second edition, of 1632, of no great rarity, but

British
libraries.

remarkable in having been presented to Sir Thomas Herbert by Charles I., with the king's autograph and his favourite motto, *Dum spiro spero*. A fourth volume is that rarest of the Aldine *Virgils*, a copy of the edition of 1505. These volumes are now preserved in the Royal Library at Windsor. There was likewise retained, and is now deposited at Windsor, a very extensive and important collection of drawings and sketches by the old masters, arranged and bound in volumes, among which are numerous drawings by Leonardo Da Vinci, Raffaele, Michael Angelo, the Caracci, Guercino, Claude Lorraine, Nicolas Poussin, and others. A selection of these in facsimile was engraved and published by Chamberlaine, 1797, large folio. Here, also, are those beautiful and masterly portrait-drawings of illustrious persons in the court of Henry VIII., by Holbein, of which Chamberlaine's imitations are so well known. The Royal Library was fed, during a period of sixty years, by an annual expenditure of about L.2000; and it is in itself perhaps one of the most complete libraries of its extent that was ever formed. It contains selections of the rarest kind, especially of scarce books which appeared in the first ages of the art of printing; in particular, it boasts of nearly forty volumes printed by Caxton, a larger number than can be found in any other library, with the exception of Earl Spencer's. It is also rich in early editions of the classics, in English history, and in Italian, French, and Spanish literature; and there is likewise a very extensive collection of geography and topography, and of the Transactions of learned academies. The number of volumes in this library is 65,250, exclusive of a valuable assortment of pamphlets—about 19,000 in number—and it appears to have cost, in direct outlay, about L.130,000. When the King's Library was added to that which previously belonged to the Museum, the number of duplicate volumes in the two collections was found to be about 21,000 volumes, of which the committee of the House of Commons recommended that not more than 12,000 should be parted with; and hence, by the gift of George IV., a clear addition was made to the National Library of more than 50,000 volumes.

Another most important addition to the library of the Grenville Museum was the bequest of the Right Hon. Thomas Grenville, in 1846. It consists of 20,240 volumes, and cost upwards of L.54,000. The books are arranged in a separate apartment; and for rarity, judicious selection, and beauty of condition, and for the number of copies of books on large paper, it is equal to any collection of the same extent that could be named. Among many choice treasures that might be specified, we may mention the *Mentz Latin Bible* (usually known as the *Mazarine Bible*), by Guttenberg, circa 1455, 2 vols., on vellum; the unique copy, on vellum, of the first edition of *Livy*, by Sweynheim and Pannartz, 1469;³ that of the first edition of *Ovid*, by Azzoguidi; a copy of the Aldine *Virgil* of 1505; a splendid set of De Bry's *Voyages*; an uncut copy of Purchas's *Pilgrims*; a first *Shakspeare*, 1623, one of the finest known; and a remarkable series of early editions of the *Orlando Furioso*. The Grenville collection was not actually deposited in the Museum until 1847. During that year was also added, by the Secretary of State for Foreign Affairs, a very extensive series of Chinese books, which had been collected by Robert Morrison, Esq. of Canton. It contains 476 distinct works, in 11,509 volumes, and is especially rich in the history and politics of China.⁴ The other most noticeable additions of recent years have been,—(1.) The collection of Hebrew

¹ The celebrated *Armada* newspaper of 1588 is now acknowledged to be a forgery, and few forgeries have been so long successful. The honour of its detection is due to Mr Thomas Watts, of the British Museum. Who was the forger can but be conjectured. The papers were elaborately concocted, and were found—partly in print and partly in manuscript—amongst the collections of Dr Thomas Birch.

² Report of the Select Committee of the House of Commons on the Royal Library, 18th April 1823.

³ This volume was purchased at Mr Edwards' sale, in 1815, for 860 guineas.

⁴ Parliamentary Return of 3d March 1848 (Sess. Paper, 139).

British
libraries.

literature formed by Dr Michael of Hamburg (who died in 1846), extending to 3970 distinct works, in 4420 volumes. This library included about 400 Bibles and Commentaries; 860 scientific works; a series of documents illustrative of the history of the Jews before and after their expulsion from Spain, and several fine specimens of early printing from the presses of Lisbon, Soncino, and Naples;¹ and, (2.) a vast and systematic selection of books in every department of literature and in all languages, chosen with express reference to the previous deficiencies of the library, as they were ascertained on a careful survey in 1843, and described in Mr Panizzi's elaborate Report of the 1st January 1845, which was subsequently printed amongst the Parliamentary papers of that year.

The aggregate of the collections, the most conspicuous of which we have thus enumerated, augmented by many minor gifts, by claims, now strictly enforced, under the Copyright Acts, and occasionally by liberal grants of Parliament for purchases, have placed the library of printed books in the British Museum on a level with the most famous European collections, and, perhaps, second only—even in point of numbers—to that of the Imperial Library at Paris. The average yearly additions amount to about 13,000 volumes; and the entire library is reckoned to contain 562,000 volumes. When Mr Panizzi, now principal librarian, became keeper of the printed books in 1837, the number of volumes was barely 240,000; so that (exclusively of the bequest of Mr Grenville), 300,000 volumes have been acquired, arranged, catalogued, and made accessible to readers, under the official rule, and mainly by the strenuous exertions of one keeper, and that, during a term of office which, compared with many official periods, marked by no such acquisitions, may almost be designated a brief one. Nor is this all. Within the same period the whole of the old library—the royal collection alone excepted—has been removed from its former habitation, subjected to an arrangement entirely new, and, to a considerable extent, has been re-catalogued, without any noticeable interruption of its public use. Assuredly, in the entire history of libraries, we meet with no parallel to these achievements; and to them will soon be added another claim to the gratitude of students, in the provision of a reading-room on a scale of unequalled magnitude, with appliances worthy of the library, the public utility of which they are designed to extend.

Depart-
ment of
manu-
scripts.

The *Department of Manuscripts* in the British Museum is not less valuable and important. It embraces several distinct collections, of which the first to be noticed is,—(1.) The *Royal* collection. This contains about 1950 volumes, which formed the other portion of the ancient Royal Library of England, presented to the nation by George II., in 1757. These manuscripts date from the reign of Richard III. to that of Charles II., and are described in a catalogue by David Casley, printed in 1734 (of which an enlarged and corrected edition is much wanted). Among these precious manuscripts, one of the most remarkable is the *Codex Alexandrinus*, a present from Cyril, Patriarch of Constantinople, to King Charles I. It is in four quarto volumes, written upon fine vellum, in uncial characters, probably between the fourth and sixth centuries, and is believed to be the most ancient manuscript of the Greek Bible now extant. Many of the other manuscripts came into the royal collection at the time when the monastic institutions of Britain were destroyed; and some of them still retain upon their spare leaves the honest and hearty anathemas which the donors denounced against those who should alienate or remove the respective volumes from the places in which they had been originally deposited. This collection abounds in old scholastic divinity, and possesses many volumes, embel-

British
libraries.

lished by the most expert illuminators of different countries, in a succession of periods down to the sixteenth century. In it are also preserved an assemblage of the domestic music-books of Henry VIII., and the *Book of Doron* of James I., in his own handwriting. It also contains several chronicles and other volumes, which appear to have been executed for Edward IV.; a volume of French romances, presented by Talbot, Earl of Shrewsbury, to Queen Margaret of Anjou, and others richly illuminated. (2.) The *Cottonian* collection, which was purchased for the use of the public in 1700, and annexed by statute to the British Museum in 1753, is especially rich in historical documents, from the time of the Saxons to that of James I. These MSS., to the number of 958 volumes, had been collected by Sir Robert Cotton, who was born in 1570, and died in 1634. Subsequently to this acquisition for the nation, a fire, on the 23d October 1731, broke out in Ashburnham House, where these MSS. were then deposited, when serious losses were sustained. From the detailed "Report from the Committee appointed to view the Cottonian Library," &c., printed by order of the House of Commons (1732, folio), we learn that "114 volumes were either lost, burnt, or entirely spoiled, and 98 others damaged, so as to be defective; so that the said library at present consists of 746 entire volumes, and 98 defective ones." Within these few years, a considerable number of the burnt fragments and damaged MSS. have been most skilfully restored. The Cottonian Library likewise contains numerous registers of English monasteries; the charters of Edgar and of Henry I. to Hyde Abbey, near Winchester, written in gold letters; and the manuscript called the *Durham Book*, being a copy of the Latin Gospels, with an interlinear Saxon gloss, written before the year 800, illuminated in the most elaborate style of the Anglo-Saxons, and reputed to have once belonged to the Venerable Beda. This collection is also rich in ancient charters, and in royal and other original letters and state papers, and comprises the correspondence of most of the great personages, not only of this country, but throughout Europe, from the earliest periods at which letters were written until the commencement of the seventeenth century. (3.) The *Harleian* collection, formed by Robert Harley, Earl of Oxford (1661–1724), was purchased in 1753 for £10,000. It contains 7639 volumes, exclusive of 14,236 original rolls, charters, and other deeds. Although somewhat miscellaneous in its character, historical literature in all its branches forms one of its principal features. It is particularly rich in heraldic and genealogical manuscripts; in the visitations of counties, and in English topographical collections; in parliamentary and legal proceedings; in originals, copies, and calendars of ancient records; in abbey registers; in manuscripts of the classics, amongst which is one of the earliest known of the *Odyssey* of Homer; in missals, antiphonaries, and other service-books of the Roman Catholic Church; and in ancient English poetry. It possesses two very early copies of the Latin Gospels, written in gold letters; and also contains a large number of splendidly illuminated manuscripts, besides an extensive mass of correspondence. It further includes about 300 manuscript Bibles or biblical books, in Hebrew, Chaldaic, Greek, Arabic, and Latin; nearly 200 volumes of writings of the Fathers of the Church; and many works on the arts and sciences, amongst which is a tract on the steam-engine, with plans, diagrams, and calculations, by Sir Samuel Morland. (4.) The *Sloane* collection, to the extent of 4100 volumes, consists principally of manuscripts on natural history, voyages and travels, works on the arts, and especially on medicine. It comprises the chief of Kæmpfer's manuscripts, with a portion of the voluminous medical collections of Mayerne, including the annals of his practice at the court

¹ Parliamentary Return of 20th March 1849 (Sess. Paper, 140).

British
libraries.

of England from 1611 to 1649; and it also contains 30 volumes of Dr Sloane's correspondence, and a considerable collection of medical and other scientific documents, with numerous manuscripts on history, poetry, and miscellaneous subjects. Some of the drawings of animals in this collection are exceedingly rich and accurate; two volumes upon vellum, are from the pencil of Madame Merian; and one relates entirely to the insects of Surinam. (5.) In 1807 the collection of manuscripts formed by the first *Marquis of Lansdowne* was added to these libraries, having been purchased by parliament for L.4925. It is divided into two parts; the first consisting of 121 volumes of the very important state papers and correspondence of William Lord Burghley, during the long reign of Queen Elizabeth; in the second there are more than 50 volumes of the papers and letters of Sir Julius Cæsar, Judge of the Admiralty, and Master of the Rolls; the collections, in 107 volumes, of Dr White Kennet, Bishop of Peterborough; several ecclesiastical registers of English priories; the correspondence of Henry Cromwell, as Chief Governor of Ireland; various ancient English chronicles; and numerous other historical, genealogical and topographical manuscripts of great importance. Amongst the minor volumes is a manuscript of Hardyng's *Chronicle*, presented by the author to King Henry VI.; a French version of the sacred Scriptures upon vellum; five volumes of Saxon homilies; and a facsimile of the Vatican *Virgil*, executed by Bartoli in 1742. To these may be added, a Chinese map, and nearly two hundred drawings, in the first style of eastern art, representing the dresses, customs, and natural history of the interior of China. (6.) Another large collection of manuscripts, about 500 volumes, almost exclusively belonging to the faculty of law, was purchased in 1813, of the representatives of *Francis Hargrave*, and cost L.8000. Amongst these, besides numerous copies of early reports, is an abridgment of equity, in 43 volumes, by Sir Thomas Sewell, Master of the Rolls. (7.) The collection of manuscripts, amounting to 520 volumes, chiefly of the Greek and Latin classics, which had been formed at a vast expense by the *Rev. Dr Charles Burney*, was purchased in 1818. Amongst these is the *Towneley Homer*, a manuscript of the *Iliad*, similar to that of the *Odyssey* in the Harleian collection;¹ two early manuscripts of the Greek rhetoricians; a volume of the mathematical tracts of Pappus; and a Greek manuscript of Ptolemy's *Geography*, adorned with maps of the fifteenth century. (8.) Two Oriental collections have also been added. One of these, made by Mr C. J. Rich, whilst British Consul at Baghdad, and purchased by parliament in 1825, contains, amongst other rare manuscripts, several copies of the Syriac version of the Scriptures, which are believed to be of great antiquity. The other, a collection made in different countries of the East, and consisting chiefly of Arabic and Persian manuscripts, was bequeathed to the Museum in the year 1827, by the collector, Mr J. F. Hull. (9.) In 1829 a small but valuable collection of manuscripts, partly relating to French history, and partly of a literary character, was bequeathed to the Museum by the last *Earl of Bridgewater*, accompanied by a small real estate, and a sum of L.5000 to be invested, and the proceeds, as they became available, applied in the purchase and binding of manuscripts. A further sum of L.7000 was bequeathed to the intent, that the interest thence accruing should be paid to the librarian or librarians having charge of the collection. In 1838 this "Egerton Fund" was largely increased by the bequest of L.2872, three per cent. consols, by the late Lord Farnborough, expressly as an addition to it, for further purchases of MSS. (10.) The last distinct collection is that of the *Howard-Arundel* manuscripts, acquired from the

Royal Society in 1831, partly by exchange, and partly by purchase, at an estimated value of L.3560. It consists of more than 600 volumes, contains many manuscripts of interest in almost every branch of learning, and is rich in materials for the history of our own country and language. The ancient rolls and charters of the Museum, many thousands in number, form another division of the department of manuscripts, with a distinct catalogue. These records and deeds partly belong to the Cottonian, Harleian, and Sloane collections, and partly are accumulated additions, being chiefly illustrative of English history, and of monastic and other possessions.

British
libraries.

These are the larger and separate collections. The Additional Manuscripts, as they are called, consist of smaller collections, which have either been acquired by purchase, or are the gifts or bequests of individuals. Amongst these may be specified, Madox's collections for the History of the Exchequer, 94 vols.; Rymer's materials for his *Fædera*, used and unused, 58 vols.; Dr Birch's historical and biographical manuscripts, 378 vols.; the decisions of the judges upon claims made in the city of London after the great fire of 1666; Sir William Musgrave's obituary; Cole's collections for a History of Cambridge and Cambridgeshire, with materials for the *Athenæ Cantabrigienses*, 92 vols.; various Coptic and other ancient manuscripts taken from the French in Egypt; Ducarel's abstracts of the archiepiscopal registers at Lambeth, 152 vols.; a long series of calendars of the *Originalia* Rolls, from 1 Henry VIII. to 2 James I.; Sir Andrew Mitchell's diplomatic correspondence with every part of Europe during his residence at the court of Frederick the Great of Prussia; Sir William Burrell's and Mr William Hayley's joint collections for the History of Sussex, 41 vols.; Mrs Banks's manuscripts on heraldry, processions, and archery, 66 vols.; Abbot's drawings and descriptions of American insects, in 17 vols. 4to; Wolley's collections for Derbyshire, 53 vols.; Sir Joseph Banks's foreign correspondence; Essex's and Kerich's collections on Gothic architecture and costumes, 49 vols.; the Stepney papers; the papers of the Count de Puisaye, chiefly relating to the Chouan war and the Royalists of La Vendée, from 1793 to 1825, in 117 vols.; the Jermyn collections for a History of Suffolk, in 51 vols.; and the still richer collections on the same subject, extending to about 160 volumes, of the late Mr Davy of Ufford; the materials collected by Archdeacon Cox, whilst employed in the compilation of his various historical and other works, in 206 vols.; numerous manuscripts, being 604 vols., illustrative of Italian history, selected from the collection of the Earl of Guilford; 310 rolls, commonly known as the Chancellor's Rolls, being duplicates of the great Rolls of the Pipe, between 9 Henry II. and 17 James I.; the smaller King's collection, being 440 vols., which formed part of the Library of George III.; the topographical collections of Samuel and Daniel Lysons, being chiefly materials for the *Magna Britannia* and *Environs of London*, 64 vols.; Egyptian Papyri, partly purchased from Mr Salt and others, and partly presented by Sir J. G. Wilkinson; an extensive collection of ancient Irish manuscripts, including copies of the Brehon Laws; a selection, made at an expense of more than L.2000, from the manuscripts possessed by Mr Richard Heber; and the voluminous Indian correspondence of the Marquis of Wellesley, from 1798 to 1805, in 1351 vols. A general enumeration of these additional manuscripts will be found in a useful volume, by Mr Richard Sims, of the Department of Manuscripts, entitled *Handbook to the Library of the British Museum* (1854, 12mo). But valuable accessions continue to be made; and at present the entire number of manuscripts, exclusive of original deeds and charters,

¹ This manuscript was purchased by Dr Burney, at the price of 600 guineas.

British amounts to nearly 40,000. Among the more important additions of the last few years, besides a series of royal and other letters, from the library of Mr Dawson Turner of Yarmouth, we may notice the splendid Bible, in two vols., of Charlemagne; the celebrated Bedford Missal, executed for John, Duke of Bedford, Regent of France under Henry VI. (which was formerly in the Harleian collection, and is now restored to it, after passing through many hands); a valuable and extensive collection of documents, illustrative of the Civil War period; the correspondence and other papers relating to the captivity of Napoleon at St Helena; and a remarkable series of papers of the Florentine family of Gualterio, extending to about 400 vols., and rich in materials for Italian history during the last century.

But no accession to this department, of recent date, can vie in interest with those venerable fragments of antiquity, which have been brought from the Nitrian desert, mainly by the zealous researches of Mr Archdeacon Tattam, and of which such excellent use has already been made by the learned author of the *Corpus Ignatianum* [IGNATIUS]. The grotesque custodians of these Syriac MSS. have been described with more than photographic vividness by Mr Curzon, and his pictures of his own experiences in the search of books, enhance our surprise that so much has been recovered. Three several consignments of MSS. from Nitria have reached the Museum since the beginning of 1843, amounting in the whole to about 600 vols. Some of these contain several distinct works, but a considerable proportion of them are more or less imperfect. It has, however, repeatedly happened, that portions of the same work have been received at different times. Probably the entire collection contains, either in works or fragments of works, not less than 1200 distinct MSS., of which the earliest are at least as old as the beginning of the fifth century, and the latest are of the beginning of the fourteenth. Amongst them are some of the oldest Biblical MSS. in existence. There is a copy of the Pentateuch, for instance, dated 464. There are nearly 30 vols. which contain various books of the Old Testament in the Peshito version, and more than 40 containing portions of the New Testament in the same version—many of them of the sixth century. Of liturgical and patristic works there are great numbers,—some of them palimpsest,—and of early and curious contributions to ecclesiastical history, not a few.¹

The catalogues of the *Printed Books* are in two series; first, the printed catalogue of 1813-1819, in 7 vols. 8vo. In the reading-room of the Museum for consultation, is a copy of this catalogue, inlaid and interleaved with manuscript additions, between the years 1819 and 1849, in 82 vols. folio. Another catalogue, still in progress, contains the subsequent additions, and extends to upwards of 300 volumes in folio. There are other special catalogues, such as of music, pamphlets, &c. The general printed catalogue, commenced in 1841, by Mr Panizzi, as yet embraces letter A only, and does not include books acquired since the close of the year 1838. An interleaved copy, with additions, is bound in 16 vols. Of the library of George III. there is a printed catalogue, 1820-1829, 5 vols. imperial folio. There is likewise a catalogue of the geographical and topographical collection attached to the library of George III., printed in one vol. folio, to match the general catalogue of this library, and also in two vols. 8vo, 1834. Of the Grenville Library, there is an excellent descriptive catalogue, the first portion prepared under Mr Grenville's own direction. It

forms 3 vols. 8vo, 1842-48. All the catalogues are alphabetical; and there is yet no general classed catalogue, although a sum considerably exceeding L.5000 was paid many years ago by parliamentary grants as "expenditure on account of a classed catalogue."² The absence of a complete catalogue, in a printed form, either classed or alphabetical, of a library such as that of the Museum, is undeniably a public inconvenience. "As are the catalogues of a library, so will be its utility,"³ is an old and true adage. No skill or industry can make a catalogue in MS. fully supply the place of one in print; and we cannot doubt that the energy which has already done so much, will in due time confer on students and on the public at large this advantage also. The printed catalogues of the *Manuscripts* are,—1. That of the manuscripts of the old Royal Library, by David Casley, 1734, in 4to; 2. That of the Sloane and other manuscripts, heretofore undescribed, by S. Ayscough, 1782, in 2 vols. 4to; 3. That of the Cottonian manuscripts, by Joseph Planta, 1802, in folio; 4. That of the Harleian manuscripts, by H. Wanley and R. Nares, 1808, in 4 vols. folio; 5. That of the Hargrave manuscripts, by Sir H. Ellis, 1818, in 4to; 6. That of the Lansdowne manuscripts, by F. Douce and Sir H. Ellis, 1819, in folio; 7. That of the Arundel manuscripts, by the Rev. J. Forshall, 1840, in folio; 8. That of the Burney manuscripts, by the Rev. J. Forshall, 1840, in folio; 9. That of the Oriental manuscripts (by various authors), published between the years 1836 and 1852, in 6 vols. folio; 10. That of the Greek Papyri, 1839, 4to; and, 11. That of select Papyri, chiefly in the Hieratic character, 4 parts, folio, 1841-1844. Manuscript catalogues of the additions in the departments of printed books, and manuscripts to the latest time are kept in the Museum reading-room. There are also separate manuscript catalogues of the collection of tracts relating to the civil wars in the reign of Charles I.; of the Cole manuscripts; of the Chinese books; of the collections of printed musical works, maps, charts, &c.

The Library of the *Royal Society* consists chiefly of printed books of science and general literature, which may be consulted by all the fellows, and from which books may also be borrowed by them under the regulations prescribed by the statutes; nor have the Society, at any time that is remembered, ever refused to lend books or manuscripts to learned men not belonging to their corporation, who had occasion to consult them. The foundation of this library was laid in 1667, by the noble gift which John Evelyn induced Henry Howard, afterwards Duke of Norfolk, to make to the Society, "to dispose thereof as their property, desiring only that in case the Society should come to fail, it might return to Arundel House, and that this inscription, *Ex dono Henrici Howard Norfolciensis*, might be put upon every book given them." This Arundel Library included a considerable number of books which had formed part of the magnificent collection of Matthias Corvinus, already mentioned. Evelyn, whilst speaking of the choice treasures it contained, goes on to add: "I should not have persuaded the duke to part with these, had I not seen how negligent he was of them, suffering the priests and everybody to carry away and dispose of what they pleased, so that abundance of rare things are irrecoverably gone."⁴ Maitland, the historian of London, writing in or about 1755, tells us that, by a bequest of Mr Francis Aston, made in 1715, and by other additions, this library had already come to "excel all the public libraries of this city in point of goodness and value."⁵

¹ We have indicated but a small portion even of the most remarkable of these Syriac MSS. Probably the best general account of them is that published in vol. lxxvii. of the *Quarterly Review* (1845).

British
libraries.

The number of volumes he states at 3625. It has now become about 41,000; and the collection is, as it ought to be, eminently rich in the literature of the mathematical and physical sciences. The transfer of the Arundel MSS. to the British Museum has been already adverted to. The titles of the books presented to the Society have been inserted at the end of the latter volumes of their *Transactions*. A carefully prepared catalogue of the scientific books was printed in 1839, 8vo, and another of the miscellaneous literature, manuscripts, and letters in 1841. There is also a catalogue in MS. of the maps, charts, drawings, and engravings, which exceed 5000 in number.¹ The Library of the *Royal Institution* was founded in 1803 by a few gentlemen, for the immediate use of the subscribers to that establishment; but any person may, upon the recommendation of a patron, always have access to it. This collection consists of nearly 27,000 volumes, including the best and most useful edition of almost every Greek and Roman classic, with the translations in English and other modern languages; the class of mathematical science in all its branches is very full, including the best scientific journals, and transactions of learned societies; and the historical department, founded on the collection of Mr Astle, which was purchased by the managers at the formation of the library, is, in its various divisions and subdivisions, exceedingly interesting. A catalogue, methodically arranged, with an alphabetical index of authors, by William Harris, was printed in 1809, in 8vo. Of this catalogue a second edition appeared in 1821, and a third in 1856. The Library of the *London Institution* was commenced in 1805, under the direction of Professor Porson, and has been admirably continued under the care, successively, of Mr Malby, of Mr Upcott, and Mr Richard Thomson. Next to that of topography, the departments of classical literature, mathematics, and history are the most amply stocked. It is also rich in bibliography, there being few works absolutely necessary to be consulted by the bibliographical student, which may not be found in this valuable collection.

braries in
London.

There is an excellent printed catalogue of this library, chiefly compiled by Mr Thomson, in 4 vols. 8vo; printed between the years 1835 and 1852.² The present number of volumes exceeds 60,000, and includes a fine series of tracts on a wide range of topics. Alike as respects compactness of arrangement and beauty of appearance, this library is a model which will repay careful study.

There are many other libraries in London worthy of notice, more especially the London (Subscription) Library, in St James's Square, established in 1841, and containing upwards of 65,000 volumes. A catalogue was published in 1853. Valuable Law Libraries are also connected with Lincoln's Inn, the Inner Temple, and the Middle Temple. The first-named collection contains 28,000 vols. of printed books and 900 MSS., and its earliest beginnings date from the year 1522. The Inner Temple Library contains upwards of 16,000 volumes of printed books, and about 500 MSS. The Middle Temple Library was founded by a bequest of Robert Ashley, Esq., in 1641. A century later it contained barely 4000 volumes, it now contains about 21,000 volumes. Of all these libraries printed catalogues

are extant. Sion College, London Wall, dates the foundation of its library in 1630,³ and contains upwards of 40,000 volumes; and, like Dr Daniel Williams' Library, in Redcross Street, founded in 1716, and opened in 1729, is rich in old English theology. Both collections are accessible to the public. That of Dr Williams, indeed, is open to all comers, and is the only one in London which is so unrestrictedly available. It contains between 20,000 and 21,000 volumes of printed books, and about 200 MSS.

British
libraries.

To John Williams, successively Bishop of Lincoln and Archbishop of York, is due the honour of having founded the first strictly public library in the English metropolis. "With strong propension of mind to enlarge the boundaries of learning," says his biographer, Bishop Hacket, "he converted a waste-room, situate in the east side of the cloisters, . . . into a goodly library, . . . and stored it with a vast number of learned volumes; for which use he lighted most fortunately upon the study of that learned gentleman, Mr Baker of Highgate, who . . . had collected the best authors in all sciences, in their best editions, which being bought at L.500, . . . were removed into this store-house [apparently in or about the year 1620]. When he received thanks from all the professors of learning in and about London . . . because they had free admittance, . . . it compelled him to unlock his cabinet of jewels and bring forth his choicest MSS. A right noble gift in all the books he gave to this *Serapeum*, but especially the parchments."⁴ The Cathedral Library of Westminster now contains 11,000 volumes;⁵ the foundation of Archbishop Williams having been liberally built upon by many succeeding benefactors. How choice a collection it is—despite some losses in the time of Charles I.—a glance at Mr Botfield's account of it will quickly show.⁶ And how suitable to its character is the habitation selected for it by the founder, may be seen in one of the charming word-pictures of Geoffrey Crayon.⁷ Books so valuable, and, if lost, so hard to be replaced, must needs be watched with careful eyes. But it is with regret we read the stringent official reply to the inquiries of the Cathedral Commissioners in 1854: "Accessible only to masters of the school, and to the Minor Canons."⁸

Nearly all the Deans and Chapters in England possess libraries of greater or less magnitude, and many of them are now liberally opened to the public under proper regulation. At St Paul's Cathedral, however, the rule is as briefly emphatic as at Westminster: "Accessible only to members of the Chapter," is the oracular response.⁹ This Library was founded by Henry Compton, Bishop of London, 1713; the old library of the Chapter having been scattered or alienated 60 years before, and part of it removed to Sion College. The Library, not having been very largely increased (there is no endowment), still carries in its aspect the impress of Bishop Compton's vigorous individuality. The number of volumes has been officially returned as 8000.¹⁰

The Cathedral Library of Durham is of almost equal value with that of Westminster, and is of somewhat larger extent, possessing about 11,000 printed volumes, besides 520 MSS. of considerable worth. It unites, with a portion of the old monastic library, the liberal benefactions of Dean

¹ Weld, *History of the Royal Society*, vol. ii., p. 474 (1848).

² This catalogue comprehends, first, a synoptical table of the classes; secondly, a plan of the arrangement, in classes, of the books themselves; thirdly, a general classed catalogue of all the books; fourthly, an index of authors' names and works; and, fifthly, an index of anonymous works, and of many different subjects, of which some account is to be found in the library.

British
libraries.

Sudbury, in the sixteenth century, and of the princely Bishop Cosin, in the seventeenth. It is so well kept up, that the printed books which Mr Botfield counted in 1848 to be 7259 volumes,¹ had increased in 1854 by nearly 4000 volumes; and is so liberally managed, that "it is accessible to all persons, without any distinction, religious or other, who are in such a position as to be deemed fairly responsible for the safe return of the books entrusted to them." At York, too, part of a more ancient library is combined with the bequests of the widow of Archbishop Matthew (1629), of Dr Fothergill, and of Dr Burgh. The collection is valuable, extends to about 8000 volumes, and is accessible to the public five days in the week. Canterbury and Exeter have each about 5000 volumes, and both collections include many books of the highest literary and antiquarian interest. With respect to Canterbury, there is a singular contrast between a statement on this point in the catalogue of 1802, and another made 30 years later, in reply to the inquiries of the Record Commission: "This Library . . . is rich in MS. materials relating to the civil and ecclesiastical history of the country," says the one.² "It is not believed that there is anything in the collection likely to be of the least public interest," says the other.³ Lincoln and Llandaff have each about 4500 volumes; Norwich, 4350; Ely, 4000; Worcester, 3600; Winchester, 3500; Carlisle, 3174. Most of the others range from 2000 to 3000 volumes; and many, even of the smallest of these ecclesiastical libraries, possess books of considerable value, which are not unfrequently the remnants of once splendid collections. It is undeniable that access to some of them has, in former times, been grossly abused, but there is evidence that the mischief has usually resulted, less from publicity than from want of proper regulations. At all events, it is certain that the strictest seclusion may be as destructive to books as the most lax use of them. That memorable cathedral library, whence certain jackdaws acquired "the expensive habit of using Anglo-Saxon MSS. to line their nests,"—as we have been lately told by a caustic Edinburgh Reviewer,—was assuredly not too public, although, in one sense, much too accessible.⁴

The Library of Printed Books, founded by Archbishop Bancroft in the reign of King James I., which, until recently, occupied the four galleries over the cloisters of Lambeth Palace, is now more worthily lodged in the noble hall built by Archbishop Juxon, and skilfully restored under the superintendence of Mr Blore. The number of volumes contained in this library is estimated at upwards of 25,000 manuscripts, many of which are of extreme rarity. In ecclesiastical history and in biblical literature, few collections contain so large a number of scarce and curious editions. The class of English topography is also extensive and valuable. The first catalogue of printed books was drawn up by Bishop Gibson; it was afterwards transcribed in a fair hand by Dr Wilkins, and has been continued by his successors in the librarianship to the present time. The manuscripts, many of which are extremely valuable, are arranged in seven sets or divisions, distinguished as *Codices Lambethiani*, *Whartoniani*, *Carewani*, *Tenisoniani*, *Gibsoniani*, *Miscellanei*, and *Suttoniani*. This department, besides being rich in copies of the sacred writings, contains Expositions of the Fathers of the Church; Missals, and Hours of the Holy Virgin; a number of papal bulls; vari-

ous treatises of Wycliffe; manuscripts relating to the history of France, and other European nations, particularly Spain, Italy, Poland, Germany, and Holland; 17 volumes in folio of the Shrewsbury correspondence; besides several letters to and from Charles II.; and certain manuscripts on heraldry and genealogy, written or corrected by Lord Burghley. But perhaps the two greatest curiosities in this collection are the ancient French version and exposition of the Apocalypse, ornamented with miniature paintings; and the Latin copy of the Apocalypse, also beautifully illuminated, which is supposed to have been written in the thirteenth century. A catalogue of these manuscript treasures, compiled by the Rev. H. J. Todd, the then keeper, was printed in 1812, in one volume folio, at the expense of the Archbishop of Canterbury.⁵ In two separate volumes, the Rev. S. R. Maitland has given a very accurate list of the earlier printed books (prior to 1550), and an index of the English books printed before the year 1600, in the Lambeth Library.

The different colleges of Oxford and Cambridge have Oxford libraries of various extent attached to them; but in each university there is at least one great or principal library, as the Bodleian Library at Oxford, and that of Trinity College, besides the Public, or University Library, at Cambridge.

The Bodleian Library, so called from the name of its Bodleian illustrious founder, was instituted towards the close of the library. reign of Elizabeth, by Sir Thomas Bodley, who, having become disgusted with some court intrigues, resigned all his employments about the year 1597, and immediately afterwards, as we have seen, undertook the generous task of restoring the public library at Oxford, which had been despoiled of its contents in the reign of Edward VI. With this view, he despatched from London a letter to the vice-chancellor, offering not only to restore the building, but to provide a fund for the purchase of books, and the maintenance of proper officers. This offer being thankfully accepted, he commenced his undertaking by presenting to the library a large collection of books purchased on the Continent, and valued at L.10,000. Other collections and contributions were also, by his example and persuasion, presented to the new library. The most important of these, perhaps, was a considerable portion of the very valuable library which had belonged to Jerome Osorius (who has been called the Cicero of Portugal), successively Bishop of Sylvas and of Algarve, in which last see he died in 1580. This library having been captured by the Earl of Essex, in the assault on Faro, in 1596, shortly after the expedition against Cadiz, part of it was by him presented to Bodley, in order to enrich the collection he was then forming.⁶ The additions thus made soon swelled to such an amount that the old building was no longer sufficient to contain them. The edifice was accordingly enlarged; and when Bodley had succeeded in enriching his collection beyond his most sanguine expectation, he drew up for its government a body of statutes, which were subsequently incorporated with those of the university. The Bodleian Library was first opened to the public on the 8th of November 1602; and has since found numerous benefactors, more especially Sir Robert Cotton; Sir Henry Saville; Archbishop Laud; John Selden; Sir Kenelm Digby; Thomas, Lord Fairfax; Dr

⁶ Monson, *Account of the Wars with Spain*, p. 32. Sir William Monson was himself captain of the Earl's flag-ship in this expedition. "The only thing that was afterwards attempted," he says, "was Pharoah, a place of no resistance or wealth, only famous by the library of Osorius, who was bishop of that place; which library was brought into England by us, and many of the books bestowed upon the new erected library of Oxford."

British
libraries.

Thomas Barlow, Bishop of Lincoln; Richard Gough; Francis Douce; Robert Mason, and others. During the years 1826-42, inclusive, the expenditure on the acquisition of printed books was L.24,368, 2s., and that on MSS. L.1839, 8s.; or, on the average, for both together, about L.1500 annually. The total expenditure during the same period was L.61,696, or about L.3600 a-year.¹ Subsequently to 1842, the Bodleian has enjoyed, in addition to its former funds, the proceeds of the noble gift of L.40,000 bequeathed by the Rev. Robert Mason. It would require a volume to contain an enumeration of the many important additions which have been made to this library by its numerous benefactors, or to admit even a sketch of its ample contents in almost every branch of literature and science. It is estimated to possess upwards of 256,000 volumes of printed books, and about 22,000 volumes of manuscripts.² The Oriental manuscripts are the rarest and most beautiful to be found in any European collection; and the first editions of the classics, procured from the Pinelli and Cr venna Libraries, almost rival those at Vienna. In a word, it is exceedingly rich in many departments in which most other libraries are deficient, and it forms altogether one of the noblest collections of which any University can boast; but, for want of a classed catalogue, the general utility of the collection is materially abridged. The first catalogue of the printed books was published by Dr James in 1600, and an enlarged edition in 1620. These were followed by Dr Hyde's in 1674, and another, of the manuscripts, was printed in 1697. A fuller catalogue of the printed books, compiled by Bowles, Fisher, and Langford, was printed in 1738, in 2 volumes, folio. A catalogue of the manuscripts relating to Oriental history, drawn up by Professor Urie, and printed in 1787, folio, has been continued in two additional volumes or parts by Drs Nicol and Pusey. In 1795 there was also printed a descriptive account of first, early, or Aldine editions of Hebrew, Greek, and Latin works contained in the library, the articles indicated being all of the greatest rarity; and in 1812 appeared the first part of a catalogue by Professor Gaisford, of the manuscript collection purchased by Dr Edward Daniel Clarke, in his travels through various parts of Europe and Asia. Another catalogue of the printed books, by the Rev. Dr Bandinel, was completed in 1843, 3 vols. folio; but such is the rapid increase that a large supplemental volume was printed in 1850, containing only the additions up to the end of the year 1847. Of the Douce Library there is a separate catalogue. A valuable catalogue of part of the Greek MSS. in the Bodleian, by the Rev. H. O. Coxe, was printed in 1853; and is to be followed by similar volumes of other divisions of these most important collections. To the great value, the liberal accessibility (as far as respects men of known attainments and established position), and the skilful arrangements of the Bodleian Library, the highest testimony has been repeatedly borne. The courtesy and kindness of its officers have also long been proverbial. Yet of late the opinion that the time is rapidly approaching when increased facilities may reasonably be hoped for has been gaining ground. As respects far-seeing liberality of expenditure in the promotion of learning, the University of Oxford need fear comparison with no institution in the world. But the more eminent that liberality, the more desirable is it that its fruits should be widely enjoyed. Nor are evidences wanting that on the part of the ruling authorities themselves there is a disposition to make further improvements in this direction.

British
libraries.

The recent inquiries of the Oxford Commissioners gave opportunity for the consideration of the general state and working of the Bodleian, and of the other Oxford libraries, of which advantage was taken for the obtainment of much valuable testimony, but not, unfortunately, including that of the Bodleian officers, the Commissioners having no power to take other than volunteered evidence. Of such as was tendered an able summary is given in the *Report*.³ The conclusions at which the commissioners arrived are briefly these:—(1.) That all the Oxford libraries should be placed under the general superintendence of the professorial delegacy previously proposed. (2.) Admitting the cogency of the objections to any indiscriminate permission to take out books, they are yet of opinion that, "under certain restrictions, and in peculiar cases," books, and even MSS., should be lent; and they refer to the precedent already existing in virtue of a considerable donation of Anglo-Saxon works made to the Bodleian, on the express condition that the Professor of Anglo-Saxon should be permitted to borrow them. Duplicates, they are of opinion, should be lent freely. (3.) They suggest an extension of the reading-room accommodation, and a larger and more accessible supply of books of reference, strictly so called. (4.) They recommend an alteration of the period of the official visitation of the library, so that it shall not take place in full term. (5.) They advise an increase in the number of sub-librarians.⁴

The commencement of the year 1857 has been marked at Oxford by a proposal which would both effectively carry out one of the recommendations we have cited, and (probably) benefit that other public library which the University owes to the generosity of Dr Radcliffe. Dr Acland, present Radcliffe librarian, suggests the conversion of the well known Radcliffe building into a Bodleian reading-room, and the removal of the books to the new Museum of Science, to which in their character they are so closely allied. Of this collection we need only say that, as a library of science, it is worthy of its founder, although it has not at all periods been managed exactly in his spirit. For many years the sum of L.500 a-year was applied out of the Radcliffe estate for purchase of books. That sum, a few years ago, was reduced to L.200, and the reduction led to the accumulation of large arrears in important scientific works, portions of which were already in the library. Radcliffe bequeathed L.40,000 in ready money, and L.250 a-year *in land* for ever. The value of the bequest has "greatly increased of late years," says Mr Strickland,⁵ "in consequence of the 'railway town' of Wolverton (containing 2000 inhabitants) having sprung up on the Radcliffe estate;" but, he adds, "though the Radcliffe trust was specially destined by its founder to public uses, no balance sheet of receipts and expenditure is ever laid before the public."

We have yet to mention, before proceeding to the libraries of individual colleges, a small but well selected collection of foreign literature—French, Italian, and German—which was commenced in 1847, as part of Sir Robert Taylor's "Institution for teaching the European languages." It contains nearly 10,000 volumes, of which about 4000 were bequeathed by the Rev. Robert Finch, and the remainder purchased by the University, to all members of which it is accessible.

The libraries of the different colleges are many of them considerable, some of them extensive, and not a few of them enriched with much that is both curious and rare. Bishop Rede contributed the first part of the collection of

¹ Accounts of the income and expenditure of the Bodleian Library, 1827-43.

² In a return to an order of the House of Commons, dated January 1849, Dr Bandinel reported the number of printed volumes as about 220,000, and of MSS. 21,000. During the years 1826-46, the average annual addition of the former was about 4480 volumes.

British
libraries.

books in Merton College, which has since been augmented, both in manuscripts and in printed books, by the liberality of succeeding benefactors. University College Library possesses a considerable collection of printed books and manuscripts, together with some works of art. Baliol College Library suffered by the depredations of the visitors appointed by Edward VI.; but the damage was afterwards repaired by a supply of books from Durham College, and by successive donations. The Library of Queen's College contains some curious manuscripts, chiefly heraldic and political, a valuable series of coins, a collection of numismatical works, and a fine orrery. This library has been largely increased of late years, chiefly in consequence of the noble gift by Robert Mason of L.30,000, to be applied to the purchase of books; and the additions thus made appear to have been admirably selected. The books of New College occupy two spacious apartments, and there is also a collection of manuscripts. The Library of Lincoln College is chiefly remarkable for a collection of Greek and Latin manuscripts made by Sir George Wheler in his travels. That of All-Souls' College is an excellent collection; it was founded by Colonel Codrington, who left L.10,000 for the purpose, besides his own library, valued at L.6000 more; and was admirably arranged, under the superintendence of Sir William Blackstone. It fills a room nearly 200 feet long. In the Library of Brazen-nose College, the ancient custom of chaining the books to the shelves was strictly observed until the year 1780, when this conservative practice was abandoned. This collection is of considerable extent and value. The Library of Corpus Christi College is enriched with a valuable set of Aldine classics, with many manuscripts and printed books, of great rarity and in excellent preservation, and with the manuscripts of Twyne and Fulman, the Oxford antiquarians. The Aldines were collected by the founder, Richard Fox. In 1755, Lord Coleraine gave to this library a large and valuable collection of Italian literature. The Library of Christ Church would probably have exceeded that of any contemporary establishment, had Wolsey been able to complete his original design, which was not only to supply it with such books as had appeared since the invention of printing, but also with copies of the most valuable manuscripts in the Vatican. This collection is principally composed of the extensive and valuable library bequeathed—the books relating to the British History and Constitution alone excepted (these being left to his son, the fourth Earl)—by Charles Boyle, third Earl of Orrery, amounting to 10,000 volumes; of that left to the college by Wake, Archbishop of Canterbury, consisting of printed books and manuscripts, with a collection of coins and medals, together estimated to be worth L.10,000; and of the contributions of many other benefactors. In 1767 the numismatical series was further enriched by the collection of British and English coins belonging to Dr Barton, and, in 1780, by that of oriental coins collected by Dr R. Brown, canon and regius professor of Hebrew. The Library of Trinity College was instituted by the founder, Sir Thomas Pope, who was also the first contributor of books. The collection was afterwards enlarged by various benefactions, and is now one of considerable extent. The Library of St John's College contains a valuable collection of printed books and manuscripts given by Archbishop Laud; whose zeal on its behalf seems (once, at least) to have led him to use his influence for the diversion thither of a rich gift¹ intended for the Bodleian; many specimens of natural and artificial curiosities, and relics of antiquity; with a collection of Greek, Roman, and English coins, bequeathed by Dr Rawlinson, along with his books. In the Library of Wadham College

British
libraries.

are many early printed books, and a good collection of classics and works on theology, together with French, Italian, and Spanish literature. The Library of Worcester College is a considerable collection, and particularly rich in architectural books and manuscripts. Exeter College Library, though of comparatively small extent, is distinguished for its liberal accessibility. Of the several collections of manuscripts, amounting to 3237 articles, preserved in the different colleges and halls in Oxford, we are indebted to the Rev. Mr Coxe for an admirable catalogue, 1852, 2 vols. 4to. A minute descriptive catalogue of the MSS. in the Ashmolean Museum, by Mr W. H. Black, appeared in 1845, 4to.

In summing up such information as they had gathered respecting the college libraries, the Oxford Commissioners suggest that a more liberal use of them may safely and discreetly be accorded; and that it is worth while to consider whether or not a co-operative arrangement might be effected to carry out, within reasonable limits, such a division of subjects as would enable the libraries to supplement, to some extent, each other's deficiencies.

The Library of Trinity College, Cambridge, is extensive, Cambridge and is contained in a very magnificent structure built by Sir Christopher Wren, being 190 feet in length, 40 in breadth, and 38 in height. The collection is separated into thirty "classes," distributed in cases of oak; and extends to nearly 43,000 volumes. Amongst other literary curiosities, there are some interesting manuscripts in the handwriting of Milton. They are contained in a thin folio volume, which was discovered by Professor Mason amongst the papers of Sir Henry Puckering, and consist of the original MS. of the *Masque of Comus*: several plans of *Paradise Lost*, composed at the period when the poet intended to have made that subject the ground-work of a tragedy; and the poems of *Lycidas*, *Arcades*, and several others. Here are also the Arabic manuscripts left by Dr Gale, and the collection relating to English antiquities by his son Dr Roger Gale; Sir Isaac Newton's copy of his *Principia*, with his manuscript notes, and his letters to Roger Cotes; and the voluminous Shakspeare manuscripts and printed books of Edward Capel, a catalogue of which was printed by Mr Steevens.² More recently Trinity College has received a collection of special interest and value by the bequest of Julius Charles Hare,—a man whose heart was as capacious as his intellect, and whose library, alike varied and choice, reflected his fine tastes. This bequest amounted to 4300 volumes, and is rich in departments of literature, and more especially of German literature, which are rarely well represented in an English library.

To Trinity Library all members of the College have free access; and undergraduates, under the authority of their tutors, are permitted to borrow as many as six books at one time. The books are seldom damaged, say the Commissioners of Inquiry into Cambridge University (in their *Report* of 1852), and they add,—“It is difficult to produce a more striking proof of the safety, under the requisite precautions, of allowing the most liberal use of a great public library.”³

The University or Public Library of Cambridge is large, University and contains much that is valuable or curious both in the library department of printed books, and in that of manuscripts. The printed books comprise a fine series of *editiones principes* of the classics, and a very considerable proportion of the productions of Caxton's press. Its chief founder was Thomas Scott (or Rotherham, as he is more usually called, from his birth-place), Archbishop of York. His earliest donations occurred about 1475; and although some of them have disappeared in the lapse of time,

British
libraries.

others yet remain. It is pleasing to notice that one of the earliest imitators of his example was a mayor of the town, John Harris by name.¹ Archbishop Parker was also a benefactor. But the library suffered many losses; and although, for a brief period, it enjoyed possession of the Lambeth collection (as it had been left at the death of Archbishop Abbot), the borrowed treasure had to be restored, when the Restoration so materially altered the relative position of Bishops and Puritans. The University Library continued to be a very poor collection until, in 1666, Tobias Rustat (one of the gentlemen of the king's bedchamber), gave L.1000 "to be laid out in the choicest and most useful books for the public library." This sum, with a like amount given to St John's College, Oxford, was invested in a Norfolk manor and advowson, and its proceeds are now L.250 a year.² Four years afterwards, Bishop Hacket bequeathed 1092 vols., which had cost him about L.1500. But the Rustat fund was the main support of the library³ until in 1715 it made the important acquisition of the fine collection that had belonged to Dr Moore, Bishop of Ely, amounting to 30,000 volumes, which were munificently purchased for 6000 guineas by his Majesty King George I., who presented them to the library, and further gave L.2000 towards fitting up the apartments destined for their reception. Bishop Moore's collection, which is singularly rich in the productions of the early English printers, had been offered to the Earl of Oxford for L.6000, and on his refusal, was purchased and presented as has just been mentioned. Cambridge may, for more reasons than this, regard its own history as affording striking exceptions to the rule of Georgian indifference to learning, even if due allowance be made for political sympathy. The benefactions of George I. and of George II. to this university exceed, in the aggregate, L.16,000 of the money of that day. This gift appears to have increased the number of volumes to 44,000.⁴ Since this date the chief benefactors have been the Rev. William Worts, and the Rev. John Manistre, both of whom left funds to be applied to the purchase of books, which, together, produce at present L.850 a-year. The copy-tax gives about 3300 volumes a-year on the average; and the University taxes each of its members six shillings a-head towards the maintenance of the library. This poll-tax produced, in 1851, L.2050, subject, however, to the duty on income.⁵ A method of classifying the books in the public library of Cambridge was long ago proposed by Dr Middleton,⁶ but no catalogue of them has yet been published. The number of printed volumes in this library is now a little above 197,000. Amongst the manuscripts—which amount in the aggregate to 3163—contained in it are,—(1), the celebrated copy of the four Gospels and Acts of the Apostles, known by the name of the *Codex Bezae*, which was presented to the university by that distinguished reformer; (2), *Magna Charta*, written on vellum; (3), several very valuable manuscripts purchased at the sale of Dr Askew's collection; (4), some curious Syriac manuscripts presented by the Rev. Dr Buchanan; (5), a Coptic manuscript written upon long narrow papyrus; (6), a Koran upon cotton paper superbly executed; (7), other Oriental MSS., some of which were presented by Burckhardt, and some by the East India Company; and (8), the celebrated MSS. relating to the History of the Waldenses, given by Sir S. Morland in 1658, several volumes of which Mr Gilly⁷ asserts have "been stolen from the University Library within the last 50 years;" whilst Mr Power is of opinion that it "is un-

certain whether there ever came into the library more than those 14 vols. which are there still."⁸ Vol. 1 of a general catalogue of the MSS. has been recently published (1857).

The Library of Corpus Christi College contains 482 Other li-
volumes of ancient manuscripts. Most of them were col-
lected after the dissolution of the monasteries. They com-
prise works of the Fathers and of the Schoolmen; a valu-
able series of documents illustrative of the History of the
Reformation, and of other civil and ecclesiastical affairs, and
the concerns of various religious houses; and some of them
are in the old Saxon character. They were bequeathed by
Archbishop Parker, and are described in Nasmyth's *Cata-*
logue, 1777. St John's College Library contains one of
the most valuable and extensive collections of books in the
university, particularly in biblical and classical literature, and
is also enriched with some first editions which came origi-
nally from the Harleian collection. The *Pepysian Library*,
preserved in Magdalen College, is so called from the foun-
der, Samuel Pepys, secretary to the Admiralty in the reigns
of Charles II. and James II., who bequeathed to this
college his very curious library, together with his prints
and drawings. It is remarkable for a collection of old
English ballads, in 5 volumes folio, begun by Mr Selden,
and continued to the year 1700; for a singular collection
of the popular literature of the day, bound up in volumes
as "penny merriments;" and for two volumes of Scottish
poetry, collected by Sir Richard Maitland, of Lethington,
and known as the Maitland manuscripts. Percy, in his
Reliques, has made a judicious selection from the former;
and, in 1786, Pinkerton published copious extracts from
the latter. Pepys's collection of prints and drawings, illus-
trative of the history of London, and his rare British por-
traits, are particularly valuable.⁹ A volume entitled, *The*
Book Rarities in the University of Cambridge, illus-
trated by original letters and notes, by the Rev. C. H.
Hartshorne, 1829, 8vo, describes many of the more valuable
printed books preserved in the Cambridge libraries.

English
town libra-
ries.

As respects *Town Libraries* of a strictly public char-
acter, England has always been poorly supplied. There
are, indeed, a few cities which have long possessed what
ought to have proved the groundwork of such collections,
but in almost every instance these small foundations of the
seventeenth or eighteenth centuries have fallen into neg-
lect. Since the passing of the "Public Libraries Act" of
1850 a new era in this matter has begun, but the libraries
that have been founded in pursuance of the legislative
measures then initiated are not limited to one portion of
the empire. Such brief account of them, therefore, as can
here be given will be most fitly placed on a subsequent
page. At present we proceed to notice the more eminent
of those English collections which are private property.

Nearly two centuries ago John Evelyn lamented "the
sad dispersions many noble libraries have suffered in these
late times; one auction . . . of a day or two having scat-
tered what has been gathering many years." "Hence it
is," he adds, "that we are in England so defective of good
libraries among the gentlemen, and in our greatest towns." He then passes in review all the collections of mark that
he had himself known, most of which had already, he says,
"passed under the spear, owing to some dark influence
and constellation now reigning malevolent to books and
libraries, which can portend no good to the future age."¹⁰

British
libraries.

as yet, to the common fate, those of Pepys, to whom he was writing, of Bishop Moore, and of Lord Berkeley, have been preserved for the public, as we have seen; but not one of those which were left in private hands has, we believe, survived to our own day, although two or three curious libraries which had escaped Evelyn's notice still exist. A few years later, John Bagford (best known for his MS. collections on the history of printing), enumerates¹ (besides some minor ones) twenty-one private collections of known importance, of which one only seems to have so continued intact. In 1810, again, we find a list of nine libraries, described as "a few of the chief private libraries in the kingdom."² Of these six have been sold; one (Mr Grenville's) has become public, and one we are unable to trace. The remaining collection, that of Lord Spencer, is unquestionably the finest private library in Britain, and is, perhaps, the finest in the world.

Earl
Spencer's
library.

Lord Spencer's Library (the greater part of which is at Althorp, Northamptonshire), is eminently deserving of mention, not so much by reason of its extent, although that is considerable, as on account of the unrivalled treasures which it contains in several departments of literature, sacred as well as secular. This library contains more than 50,000 volumes, exclusively of the Cassano collection purchased in 1820, and was chiefly formed by George John, second Earl Spencer; the greater part of the old library of Althorp, so frequently mentioned by Evelyn, having long since become the foundation of the fine collection at Blenheim. Dr Dibdin, in his *Bibliotheca Spenceriana*, has devoted six volumes (in addition to the Cassano volume) to a bibliographical description of the books printed during the fifteenth century, or otherwise remarkable, either for intrinsic worth, or for beautiful typography.³ The foundation of the choicer part of the library was laid by the purchase, about 1790, of the collection of Count Reviczky, a Hungarian nobleman who had at first occupied himself in accumulating rare and curious works of a peculiar description. The choice condition and splendour of the entire collection are such as render it unrivalled.⁴ But, perhaps, its most remarkable feature is the unexampled assemblage to be found in it of works illustrating the origin and progress of typography. It contains several books, consisting of impressions taken from carved wooden blocks previously to the invention of metallic types, and thus exhibiting the earliest specimens of stereotype printing. In others, engraved figures constitute the principal part, to which is added a small proportion of text, and only one side of the leaf is employed, the other being left blank. Such is the *Ars Memorandi notabilis per figuras Evangelistarum*, supposed to have been thrown off previous to the year 1430, and consisting of a number of rude cuts of the principal events recorded in the Gospels, with text on the opposite page; and such, also, is the *Ars Moriendi*, the subject of which is a sick man in bed, surrounded by grotesque and hideous figures of angels and demons. The taste of the time inclined to the monstrous or the absurd. In the first-named work St Luke is represented by a bull standing on his hind legs, whilst St Mark is depicted as a rampant lion. The *Historia Veteris et Novi Testamenti, seu Biblia Pauperum*, also in this collection, is supposed to have been executed prior to the year 1400, and is by some considered as the earliest specimen of block-printing. Amongst the

British
libraries.

early printed and scarce Bibles in the Althorp Library may be mentioned the "Mazarine Bible," (already noticed in our account of the Grenville Library); another Bible, supposed to be the work of Albert Pfister, prior to 1460; Fust and Schœffer's Bible, 1462, on vellum; that by Sweynheym and Pannartz, 1471; the first edition of the greater portion of the Old Testament in Dutch, 1477; Prince Radzivil's Bible in Polish; besides other early copies in the different languages of Europe. This collection also contains the Latin Psalter of Fust and Schœffer, printed in 1457, being the first printed book to which a date is affixed; and another of nearly equal rarity, printed in 1459. Many of the earliest editions of the classics, beautiful copies on vellum, and works of all the celebrated printers of the fifteenth century, add to the value of this unrivalled collection. The Cassano Library,⁵ purchased by Earl Spencer in the year 1820, and the greater part of which was soon afterwards united with his general collection, formed a valuable addition to the Althorp Library. Amongst other rarities, it contained the famous edition of Horace, printed at Naples in 1474, by Arnoldus de Bruxella, of which there is no other known copy; that of Terence, printed by Riessinger, without date, but probably not later than 1471; the earlier productions of the Neapolitan press; rare editions of the early Italian classics; specimens of early printing at Rome, including the edition of Juvenal, printed in the smaller fount of Ulric Han; together with all the rarest editions of Virgil, Horace, Ovid, and other Roman poets.⁶ The far-famed Boccaccio's *Decamerone*, printed by Valdarfer in 1471, which, at the Roxburghe sale, in 1813, produced the astounding price, for a single volume, of L.2260, was afterwards acquired by Earl Spencer for a sum considerably less than half that amount. The Library occupies a noble suite of rooms, the entire length of which is 220 feet.

Many fine and even extraordinary collections have been both formed and dispersed by public auction within living memory. Such, for example, were Heber's, Bindley's, Sir Mark Sykes', Hibbert's, George Chalmers',⁷ the Duke of Sussex's, and the Marquis of Blandford's. Of other private libraries, such as those of the Duke of Marlborough at Blenheim, of the Duke of Devonshire at Chatsworth, of the Earl of Ellesmere at Bridgewater House, and other noble collections, interesting particulars might be given; we shall, however, only notice one other private collection, that of Sir Thomas Phillipps, Bart., at Middlehill, Worcestershire, which, we earnestly hope, may long escape any such fate. It is a noble library, far exceeding in intrinsic worth its relative extent, although the number of volumes approaches 50,000. The specialty of the collection consists in the very exceptional fact that the number of manuscripts far exceeds that of printed books. Its formation has been prosecuted with energy, and with large outlay, during more than thirty years, and the result is now a thing which, once seen, will never be forgotten. The most striking peculiarity of aspect lies in the long ranges of boxes, tier above tier, and of uniform size, each with its falling front, in which nearly all the books are lodged; not, indeed, for concealment, but by way of safeguard against that terrible foe of libraries—fire. The books are almost as little visible as are those of the Vatican, but how different their accessibility is known to a considerable number of students who have profited largely by their contents.⁸

Library of
Sir T. Phil-
lipps.

In Scotland, at an early period, there were collections of

land.

manuscripts belonging to most of the religious or monastic establishments; and there are preserved brief inventories of books belonging to some of the cathedral churches.¹ We also find notices of private collections during the end of the fourteenth and the following century. But the earliest public library was that of the University of St Andrews. In a *Prognostication*, by Jasper de Laet, printed abroad in 1491, and addressed to William Schevez, Archbishop of St Andrews, who filled the see from 1478 to 1497, the author celebrates that prelate for his love of science, and for enriching the library with many precious books and manuscripts of all kinds.² The library still exists, but the *plures codices* referred to have long since been dispersed. The name *codex*, however, was applied to printed books as well as manuscripts; and volumes are occasionally met with having the name of Schevez, and other early collectors, written or impressed with their arms on the books. The library of James IV. is alleged to have been carried by the English from Holyrood in 1547.³ One book, belonging to James V., being Bellenden's *Chronicles of Scotland*, translated from Hector Boece, and printed on vellum, about 1541, and having the royal arms on the sides, is now preserved at Hamilton Palace; and the original manuscript of the same work, written in 1536 or 1537, and similarly ornamented, is at Dupplin. Mary Queen of Scots was also a collector, and partial lists of her books, including French poetry and romances, have been printed, and a few of the volumes are known and highly appreciated.

Advocates'
Library,
Edinburgh.

The design of forming a library was adopted by the Faculty of Advocates as early as the year 1680. The author and active promoter of the scheme was Sir George Mackenzie of Rosehaugh. It was originally intended that it should consist merely of the works of lawyers, and of such other books as were calculated to advance the study of jurisprudence. This may be inferred from the inaugural address delivered by Sir George Mackenzie, when the library was first opened, and from several other papers relative to the subject. At its commencement, this library had no certain fund allotted for its maintenance. It depended upon and owed its increase to the donations of benefactors, together with such sums as the Faculty from time to time placed at the disposal of the curators. In the year 1700, the apartment where the library was kept being nearly destroyed by fire, it was removed to the place which, in part, it still occupies, namely, the ground floor of the Parliament House. During the nine years immediately following, it must have increased considerably,⁴ since by the act passed in the eighth year of Queen Anne's reign, the privilege of receiving a copy of every book entered at Stationers' Hall was conferred upon it, along with eight other libraries, four of which were Scottish, being those attached to the universities of St Andrews, Glasgow, Aberdeen, and Edinburgh. It is the only library in Scotland which retains this privilege.

The department of printed books comprehends, in a greater or less degree, almost every branch of science, philosophy, jurisprudence, literature, and the arts. As might be ex-

pected, the collection of law-books is very extensive. The historical collection, also, is exceedingly valuable. The series of Greek and Roman classics, though it cannot vie with some others, is also extensive, and includes several first, and many early editions. The library is rich in modern poetry and belles-lettres, and, besides the miscellaneous department, contains a very considerable collection of voyages and travels. It is defective in the great branch of mathematical and physical science; in archæology or antiquities; in early as well as modern Italian literature; and, generally, in foreign literature of a recent date. Amongst the separate collections are, the Astorga Library, the Thorckelin collection, and that of old Scottish books. A collection of Spanish books, amounting to about 3400 volumes, which had formed part of the library of the Marquis of Astorga, was purchased from a London bookseller in 1824, for the sum of L.3000. The Thorckelin collection, so called from Professor Thorckelin, to whom it originally belonged, contains about 1200 volumes, chiefly on northern history, antiquities, and law. Of the Scottish books, those relating to old Scottish poetry are exceedingly rare and curious.⁵ There is also a collection of German dissertations, amounting to upwards of 100,000, called Count Diedrich's collection, which was purchased by Sir William Hamilton, on account of the library, for the trifling sum of L.80. This library is not rich in typographical rarities; with the exception of the Mentz or "Mazarine" Bible, and some specimens of early printing in Scotland. The total number of printed volumes contained in the library was, in 1849, officially returned to the House of Commons, as 148,000.⁶ "No return," it was added, "can be made of the works received by the Advocates' Library, under the copyright acts, no account having been kept." If, however, we assume (1), that the number of volumes yearly added to the library from this source must nearly correspond with the *average* number so received by other libraries having the same privilege; and (2), that the books received are preserved; it will follow that the aggregate number of volumes must now (1857) have increased to at least 172,000. As to this copyright increment, there is a passage in the evidence of Mr Maitland (then Solicitor-General, and subsequently Lord Advocate for Scotland), before the Select Committee on Public Libraries of 1849, which has a claim to be quoted:—"As the library is the private property of the Faculty," said the Solicitor-General, "it may at first sight appear difficult to find grounds for legislative interference with it. But . . . the possession of the privilege of Stationers' Hall gives, in my view, a very sufficient ground. . . . It could never have been the intention of the statute to give that privilege to injure authors and publishers by immediately converting the books so given to the ordinary purposes of a circulating library. . . . As the books come from the Stationers' Hall, they are boarded, and are immediately placed upon the public tables. In this way, not only . . . ephemeral literature, but works of the highest value, published

British
libraries.

of the *Archives des Missions Scientifiques*, published by the French Ministry of Public Instruction, will be in possession of better testimony than ours on this point.

¹ *Registrum Episcopatus Glasguensis*, vol. i., p. xliii.; vol. ii., p. 344. *Registrum Episcopatus Aberdonensis*, vol. ii., pp. 127-137, 154-159.

² *Dunbar's Poems*, by Laing, vol. ii., p. 348, Edinburgh, 1834, 2 vols. 8vo.

³ *Archæologia Scotica*, vol. iv., p. 1-13.

⁴ In 1707, the library received a large donation of books in natural history, to which many of the most costly and magnificent works on that branch of science have since been added.

⁵ The first productions of the Scottish press preserved in this library should not pass unnoticed. One of these is a unique volume of poetical tracts, printed by Walter Chepman and Andrew Myllar in 1508; of which there exists a limited reimpression in fac-simile, 4to, 1827. The next is a copy of the well-known *Breviarium Aberdonense*, of which a careful republication has recently appeared. This Breviary was composed by, or under the direction of William Elphinstone, then Bishop of Aberdeen, for the use of his cathedral, and printed in the year 1509; and it consists of two volumes in small octavo, but of the first volume the title-page and some leaves at the end are wanting. The second volume, printed in 1510, has at the beginning a calendar, and at the end these words:—"Opido Edinburgensi impresso jussu et impensis honorabilis viri Walteri Chepman ejusdem opidi Mercatoris quarto die Junii millesimo CCCC decimo." On the outside of this leaf is a wooden engraving representing a man and woman clothed in skins of beasts, with their shoulders bare, and their heads adorned with wreaths of flowers; whilst between them stands a tree, from which is suspended a shield with W. C. in cipher. The most perfect copy known is that preserved in the Library of the University of Edinburgh.

⁶ *Public Libraries: Abstract of Supplemental Return*, 9th March 1849 (Sess. No. 18), p. 2.

British
libraries.

in this country, are immediately converted to common circulating purposes. . . . They do not remain a public deposit, but are, to a great extent, so destroyed by the mode in which they are used, as to be unfit to be deposited in a great public library."¹

The department of manuscripts, though not so extensive as in some other libraries of the same class, is nevertheless of great interest and value with reference both to the civil, and still more to the ecclesiastical history of Scotland. Soon after the foundation of the library, the Faculty appear to have turned their attention to the collection of MSS. and this important department now consists of nearly 2000 volumes. The most valuable portion of the MSS. is that which relates to the ecclesiastical state of Scotland immediately preceding the era of the Reformation, and includes, amongst other things, thirteen chartularies or volumes of records of the different religious houses, which escaped the general destruction in which the edifices themselves were then involved. Considerable light is also thrown on the civil and ecclesiastical history of Scotland at a later period, by the documents and other materials contained in the collections of Sir James Balfour, Sir Robert Sibbald, and Wodrow the historian. Balfour's collection, which consists of upwards of 150 volumes, was purchased in 1698. About the half of it consists of original state papers, and several very curious royal letters written in the times of James VI. and Charles I. One of the volumes consists of letters by Anne of Denmark, queen of James VI.; by Prince Henry and Prince Charles, his sons; by the Princess Elizabeth, his daughter; and by the Elector Palatine and his son to James VI., entirely of a familiar nature. From these, some partial selections were made by Lord Hailes, and printed in 1762 and 1765. Most of these chartularies, as well as the more important original letters and state papers referred to, have been published by the Bannatyne Club and other literary associations. The *Annals of Scotland*, compiled by Sir James Balfour, were also printed in 1824, 1825, in 4 volumes 8vo. But there still remain unprinted some MSS. on genealogy and heraldry, besides a considerable number of curious documents. Sir Robert Sibbald's collection, consisting of upwards of 30 volumes, was purchased by the Faculty in 1723. It is chiefly of a topographical and literary character. Wodrow's collection is much more voluminous, consisting of upwards of 160 volumes. It was chiefly from this immense mass of materials that that laborious writer compiled his *History of the Sufferings of the Church of Scotland*; other portions have been published by the Wodrow Society; but by far the greater portion of the collection, containing many original letters and papers, is still unprinted. His correspondence with many eminent literary characters, embracing a period of more than thirty years (from 1694 to 1726), and extending to about 30 volumes, is also full of curious information respecting the literature and history of the period to which it refers. A collection of original documents belonging to the reigns of James V., Queen Mary, and James VI., was presented to the library by the Earl of Balcarras. These MSS., consisting, as now arranged and bound, of 9 volumes folio, include letters from James V., and the Earl of Arran, governor of the kingdom in the infancy of Queen Mary, to the Kings of England, France, Norway, and Portugal, to the Duke of Guise, the Earl of Suffolk, and others, from 1539 to 1542; also original letters by Queen Mary, addressed to her mother the Queen-dowager, during the early years of that beautiful but ill-fated princess. This department also contains Lord Fountainhall's collections, in his own handwriting,

British
libraries.

including his decisions, historical notices, diary, and other matters; from which his published papers have been selected. We may likewise notice the curious and interesting papers of James Anderson, Murray of Stanhope, the correspondence of Gough and Paton, with portions of the MS. collections of George Chalmers and of General Hutton, which have been arranged and bound in several folio and quarto volumes; and also those collected by the Rev. James Scott of Perth, consisting of about 20 volumes folio, and comprising the Blackfriars' Charters, in 3 volumes; extracts from the records of the Church of Perth, in 4 volumes; the records of the Hospital from 1577 to 1732; extracts from the records of the Kirk-session; a chronicle; and a register of baptisms and deaths.

The same department includes a number of manuscripts on heraldry, genealogy, and Scottish law, besides many of a miscellaneous nature. It also contains several early MSS. of the classics, and a few illuminated missals. Amongst the former may be mentioned a very fine copy of Horace, belonging to the thirteenth century; the *Plays* of Terence, executed in the year 1436; a copy of the *Epigrams* of Martial, in perfect preservation, which, from the style of the writing, may be ascribed to the ninth century, and is supposed to be one of the most ancient manuscripts of the *Epigrams* extant;² a copy of Valerius Maximus, beautifully written on vellum, dated 1398; Lactantius, *De Opificio Dei*, a gem of its kind; the mathematical collections of Pappus of Alexandria, written in beautiful Greek, with admirably executed diagrams; besides portions of several classics, as Cicero, Ovid, Juvenal, and Persius, all of considerable antiquity. A manuscript copy of St Jerome's translation of the Bible, supposed to have been written about the tenth century, and said to have been found in the Abbey Church of Dunfermline during the reign of David I.; the Auchinleck Manuscript is a collection of ancient English poems and metrical romances, written about the middle of the fourteenth century: it is so named after the donor, Alexander Boswell of Auchinleck, one of the Lords of Session, in 1744 (from this volume Sir Walter Scott printed the *Romance of Sir Tristrem*). Bannatyne's Manuscript, rebound in 2 vols. folio, being a miscellaneous collection of Scottish poetry, and "written by Geo. Bannatyne in the time of his youth, 1568,"³ likewise adorns this department of the library. It was from Bannatyne's collection that Allan Ramsay selected the poems which were printed in the *Evergreen*; and from the same source Lord Hailes extracted a volume, which was printed in the year 1770. In 1825 about 100 volumes of Icelandic MSS., amongst which are several ancient Sagas, were purchased of Professor Finn Magnuson, of Copenhagen, and added to the collection; and in the following year, Mr Elphinstone, and Mr Erskine, formerly of Bombay, presented to the library some valuable Persian and Sanscrit MSS. A beautiful manuscript of the Hebrew Bible, in 2 large folio volumes, was purchased in Germany; and the Pentateuch, besides the original, has also the Chaldaic paraphrase. A manuscript of the *Corpus Juris Civilis*, well executed, but of uncertain date and doubtful authority, and another of the *Pandects*, were likewise purchased several years ago.

The library is governed by five curators, one of whom goes out of office annually by rotation, and another is elected in his stead from amongst the body of the Faculty. Under the curators are a principal keeper or librarian, and several assistants. The library is supported partly by the acquisitions which it is continually making in virtue of the right conferred upon it by the Copyright Act, and partly by an annual sum paid to the curators for the use of the establish-

¹ *Minutes of Evidence of Select Committee on Public Libraries*, 1849, Q. 1444, p. 94.

² An account of this manuscript was published by Mr Dalrymple in 1811, in 8vo, two copies of which were printed in vellum.

³ Bannatyne's manuscript was presented to the library, in the year 1772, by the Earl of Hyndford.

British
libraries.

ment out of the revenue of the Faculty. Strangers arriving in Edinburgh are freely admitted to the library; and any one who is at all known is never denied the privilege of resorting to, and of reading or writing in the library. Very eminent men have been keepers of this collection, particularly Thomas Ruddiman, David Hume, Adam Ferguson, and Dr Irving, a learned civilian, well known by his *Life of Buchanan*, and other works.

The first volume of the general catalogue was begun in 1735, and printed in 1742, under the superintendence of the learned Ruddiman and Walter Goodall; and this was followed by two others in 1776 and 1807, all in folio; but the MS. additions which have since been made are at least equal to other two printed volumes of the same size. A catalogue of the law books was printed in 1831, in octavo; but an entirely new catalogue of the whole contents of the library has been for several years in course of preparation.

Library of
the Writers
to the
Signet.

The Library of the Writers to Her Majesty's Signet, is an excellent miscellaneous collection of books in the sciences, law, history, geography, statistics, antiquities, literature, and the arts; and it has recently been rendered much more accessible by the ample and spacious accommodation provided for it. It is contained in two large and beautiful apartments, both under the same roof, with small rooms adjoining. The books are so arranged in classes or departments as to afford facilities for reference, and to exhibit, in a general way, the component parts or branches of the collection. The choice and condition of the books generally deserve particular notice; and, indeed, this library, though supported exclusively from the funds of the society to which it belongs, possesses some of the noblest and most expensive works ever published, either abroad or at home. The number of volumes may be estimated at nearly 45,000. There is a classed catalogue, formed on De Bure's system, and very skilfully executed, which was printed in the year 1805; but this applies only to a small portion of the collection, which has been very greatly increased since the catalogue in question was prepared. An alphabetical catalogue of the whole collection has been printed, in progressive parts, with (1836) a *classed index*, which, in a great measure, supplied all the advantages of a catalogue according to subjects. A classed catalogue of the department "Jurisprudence" has recently (1856) been completed; and it will probably be followed by other portions of a general catalogue. The government of the library is vested in a body of curators, elected by the Society. Here, as in the case of the Advocates' Library, the utmost liberality is shown to strangers, and to literary men generally.

Edinburgh
University
Library.

Like most other college libraries, that of the University of Edinburgh was founded by a donation; and, for a long period, the casual contributions of benefactors constituted its principal means of support, as well as of increase. In 1580, Mr Clement Littill, commissary in Edinburgh, bequeathed his library, consisting of about 300 volumes, chiefly theological, "to Edinburgh and the Kirk of God," and this small collection was afterwards transferred by the Town Council to the College, which they were then instituting. Littill's bequest thus laid the foundation of the University Library. But it was subsequently augmented, partly by the donations of citizens, and still more by the benefactions of persons who had received their education in the College. Amongst the latter may be mentioned Dr Robert Johnston, the Rev. James Nairne, and, above all, Drummond of Hawthornden, one of the favourite sons of the Scottish muse. His gift is the more valuable, because,

British
libraries.

independently of the high reputation of the donor, the collection is enriched with many rare specimens of our early literature. In 1627 a list of these was printed in *Auctarium Bibliothecæ Edinburgensæ*; but he gave several other books in 1628 and 1635. These are now collected together. A catalogue of Nairne's books was also printed in 1678. The acquisition of Dr Andrew Balfour's collection in 1697, which served as the foundation of the College Museum, has been much less fortunate. In 1764 the Library of the Incorporation of Surgeons was added to that of the College, in consequence of an agreement, which has eventually proved eminently advantageous to the former body, whatever may be the case in so far as regards the interests of the University. This collection consisted of about 500 volumes, almost entirely professional, and now of very little value. The principal bequest which the library has more recently received is that of Dr William Thomson, who, in 1808, left it about 600 volumes, chiefly on medical subjects. In a testamentary bequest by the late General Reid, who was educated at this university, mention is made of the library, as an object to the improvement and extension of which his munificent legacy is, amongst other things, to be applied. The funds by which the library is maintained, and its progressive enlargement secured, are matriculation fees, fees on graduation in three faculties, a donation of L.5 from each professor on his induction, an annual payment of L.20 by the College of Surgeons, occasional donations of books, and a grant of L.575 from government, in compensation of its abolished privilege. The ordinary management of the library is vested in nine curators, appointed annually by the *Senatus Academicus*, four of whom retire from office every year, and are immediately succeeded by an equal number of such professors next in seniority, as are willing to undertake the duty. Four of these curators are from the medical, one from the theological, and four from the general department, including classes neither medical nor theological.¹ This library consists of somewhat more than 100,000 volumes, and about 400 MSS. The accommodation provided for it is of the most magnificent description, the library-hall being by far the most spacious and noble apartment in Scotland. As to the collection generally, it contains much that is valuable, and a good deal that is both curious and rare; but, considered as a repository of varied information in science and literature, it is unequal and defective. Its most ample department is that of medicine, a purely professional one, and more largely replenished than any other with obsolete matter. Those of natural philosophy and natural history are tolerably supplied with the works belonging to them. But in classical literature, including under that head all that relates to the exposition and illustration of the ancient authors, there are perhaps few great libraries more defective.² It is to be hoped, however, that every exertion will be made to give to the collection that character of generality, founded upon the possession of all that is most useful and interesting in every branch of knowledge, which constitutes the best recommendation of a great public library. This it is which has imparted to the Library of Göttingen its great and acknowledged excellence. The only catalogue yet printed is one of the books relating to medicine, arranged alphabetically according to the names of the authors.³ The library is, of course, primarily for the use of members of the university, and of the College of Surgeons. "But literary gentlemen, or others, who have occasion to consult or to borrow books, on application to the curators, or to individual professors, willing to be responsible for them, are allowed every prac-

British
libraries.

ticable facility.¹ In addition to the public, there is attached to the University a theological library, founded towards the close of the seventeenth century, and now containing about 5000 volumes. In connection with the New College, established by the Free Church, there is an excellent library chiefly of works on theology, amounting to nearly 25,000 vols. Among other special libraries in Edinburgh, there are those of the Royal College of Physicians, founded in 1682, having, according to the printed catalogue in 1849, 9000 volumes; the Royal Medical Society, instituted 1737, with upwards of 16,000 volumes; the Philosophical Institution; the Watt Institution and School of Arts; the Solicitors before Supreme Courts; Solicitors-at-Law; Edinburgh Subscription Library, 1794; Select Subscription Library, 1800; and Edinburgh Mechanics' Subscription Library, 1825.

Glasgow
University
library.

The history of the Library of Glasgow College, though curious and interesting, is chiefly a register of the numerous successive donations by which it was gradually formed. Amongst the names of its early benefactors we find that of George Buchanan, who, it appears, presented to the college 20 volumes, consisting entirely of Greek works, chiefly classics,² and made other benefactions, the extent of which cannot now be ascertained. This library is stated in the official return of 1849, to have contained at the close of the preceding year, 58,096 volumes of printed books, and 242 MSS.³ It receives £707 a-year from the Consolidated Fund for the purchase of books, and must now (1857) contain at least 75,000 volumes. The other funds for its support are derived from the interest of certain small sums bequeathed by individuals, from graduation fees, and from the contributions of students, including the interest accruing from the deposit money. Amongst the manuscripts in this library are several volumes by Wodrow, principally on biography. A catalogue of the printed books, by Professor Arthur,⁴ appeared in 1791. Two supplements have since been published in 1825 and 1836.

St Andrews
University
library.

There was at an early date a library in each of the Colleges at St Andrews,—one such library has been referred to already, as the earliest Scottish collection on record,—but no mention is made of a University Library until about the commencement of the seventeenth century. At that period there occurs a notice of such a collection; and a catalogue of its contents, made at the time, is still extant, the books being chiefly presents from James VI. and the members of his family. With this public University Library, those of St Salvador's and St Mary's Colleges came, in process of time, to be incorporated; and, about the year 1780, that of St Leonard's College, the best of the collections, was conjoined with the rest. As now constituted, the library is supported by the interest of money made up out of the excess of the receipts above the expenditure of its funds; the surplus rent of some teinds and lands held in lease from the Exchequer; certain fees on graduations; together with the grant of £630 a-year from the Consolidated Fund. It contained in 1848, 51,265 volumes of printed books,⁵ and now contains about 61,500 volumes, and 63 MSS.; it is, upon the

whole, an excellent collection. There is a printed alphabetical catalogue to the year 1826, and a progressive manuscript one since that time. There is also a classed catalogue in manuscript. All students attending the University have the use of the library, free of expense, both for consulting and for borrowing books. Other persons, whether resident in St Andrews or elsewhere, if engaged in literary or scientific investigations with a view to publication, may borrow books, under guarantee, on application to the Senate, and free access to the library for the purpose of consulting is granted to any respectable person.

British
libraries.

There is reason to believe, that from the first institution of the University of Aberdeen there was a collection of books at King's College, but no particular record of the library or its management, prior to the year 1634, is now to be found. The collection contains about 37,000 printed volumes, and 74 MSS. Amongst the latter are one of the splendid copies of the Koran said to have belonged to Tippoo Sahib; a work on Hindu theology, written upon fine vellum, and rolled on a piece of ivory, like the *volumina* of the ancients; and a Shaster in Sanscrit, written on the leaves of trees. The grant assigned to Aberdeen, in lieu of the copy-tax, amounts to but £320 annually, that being the estimated average value of the books which it had actually received. The official reply to the inquiries as to public facilities runs thus:—"The library is accessible to all the Professors and Lecturers of this University and of Marischal College, as well as to all graduates and students of the former, on depositing the value of the books received."⁶ This state of things has long been unsatisfactory to Marischal College; the Supreme Civil Court of Scotland having long since decided that the books acquired by copy-tax were to be kept in King's College, "for the use of both colleges." But, as of late the old project for a reunion of the colleges has been revived, it is probable that this minor question, with others of greater moment, may be satisfactorily solved. The separate Library of Marischal College had its origin in a collection of books made at the time of the Reformation by the magistrates of Aberdeen, and partly procured from the suppressed monasteries of that city.⁷ The number of printed volumes in it is about 12,000, and of MSS., 100. The funds for augmenting this library arise from fees of graduation, and are of very small amount.

The Library of Trinity College, Dublin, owed its establishment to a singular incident. In the year 1601 the Spaniards were defeated by the English at the battle of College, Kinsale. Determined to commemorate their victory by some permanent monument, the soldiers collected amongst themselves the sum of £1800, which they agreed to apply in the purchase of books for a public library, to be founded in the then infant institution of Trinity College.⁸ This sum was placed in the hands of the celebrated Ussher, who proceeded to London, and there, in conjunction with his friend Dr Challoner, purchased the books necessary for the purpose. It is a curious coincidence, that Ussher, whilst occupied in purchasing these books, met in London Sir Thomas Bodley, engaged in similar business, with a view to the

⁵ *Supplemental Return*, *ut supra*, p. 2.

⁶ *Ibid.*, p. 3.

⁷ These books were retained in one of the churches, under the care of the magistrates, and were called the Town's Library, and *Bibliotheca Ecclesiastica*. On the 19th of May 1624, Mr Thomas Reid, Latin secretary to James VI., bequeathed his books to the college, and left 6000 merks to the town, the interest of which was to be applied as a salary to a librarian. Reid's collection was afterwards united to the *Bibliotheca Ecclesiastica*, and to the books bequeathed by Dr Liddel, and other benefactors; and the whole, forming one collection, was deposited in the college, of which it now constitutes the public library. (See Appendix to the *Report of Commission on the Universities and Colleges of Scotland*, p. 361.)

⁸ Parr, *Life of Ussher* (1686), p. 10. The writer's words are too striking to be passed over: "That army," he says, "resolved to do some worthy act that might be a memorial of the gallantry of military men, and of that due respect they had for true religion and learning." The college had been established nearly ten years before, but no mention of a library occurs in its accounts until the audit of 1605. (*Report of Dublin University Commission*, July 1852).

British
libraries.

augmentation of his famous library at Oxford, and established with him a friendly intercourse and co-operation. From this commencement, the Library of Trinity College was at different periods increased by many valuable acquisitions, including, after many obstacles and long delay, that of Ussher's own collection, consisting of nearly 10,000 volumes. It had been the primate's intention to bequeath what remained to him of his noble library to Trinity College, but the loss of his revenue compelled him to leave it as a provision for his daughter. Both Cardinal Mazarine and the King of Denmark made liberal offers for its purchase, but an order of the Council of State prevented its exportation. "At length," says Ussher's biographer, "it was bought by the soldiers and officers of the then army in Ireland, who, out of emulation to the former noble action of Queen Elizabeth's army, were incited . . . to the like performance; and they had it for much less than . . . had been offered for it before."¹ In a few years, its growing magnitude requiring a corresponding increase of accommodation, the present library-hall, a magnificent apartment of stately dimensions, was erected in the year 1732. In 1726 Dr William Palliser, Archbishop of Cashel, bequeathed his library of 4109 volumes. Ten years later Dr Gilbert gave his own library of 12,749 volumes, and arranged them, in person, on the shelves. In 1787 the entire collection consisted of 36,047 volumes of printed books, and 1111 volumes of MSS. and prints. When the French invaded Holland in 1794, the collection of Pensionary Fagel, amounting to 17,537 volumes, was removed to England, where, in 1802, it was purchased by the College for the sum of L.10,000, towards which sum L.8000 was granted for the purpose by the trustees of Erasmus Smith.² Another important addition was made to the original collection by the acquisition of the select and valuable classical and Italian books which had belonged to Mr Quin; and a considerable increment of books has also resulted from the copy-tax, by which the college has profited since the year 1801. Altogether, the Library of Trinity College now forms one of very high value, and is under admirable management. In the department of printed books, the total number of vols., in September 1851, amounted to 107,650. When reckoned in August 1856, there were 126,095 printed vols., and 1600 MSS. The Ussher MSS. amounts to 693, the Stearne MSS. to 135, the Stearne and Alexander to 77, and those presented by other persons to upwards of 400 volumes. Ussher's MSS. may be classed into Bibles, and parts of Bibles, with commentaries; breviaries, missals, Roman rituals, the works of the Fathers, and oriental writers; systematic, scholastic, and polemic writers; catalogues, philosophical, medical, and historical; and, lastly, Irish histories and genealogies, civil and ecclesiastical. The subjects of the Stearne MSS. are somewhat similar to these, with the exception that some of them treat of forensic matters. In this department of the collection, there is preserved the Gospel of St Matthew, along with other fragments of Scripture, written in Greek capitals, and ascribed by Dr Barret to the sixth century. The total number of MSS. is about 1620. In 1848 a new reading-room was completed and opened for the use of readers.

As to catalogues, this library will soon be much better supplied than it has hitherto been. A very elaborate alphabetical catalogue (of which we have seen a portion) has been long at press, and is now advancing towards completion. Of the Fagel collection, the printed sale catalogue (by Paterson) has always been useful, both from its plan and

its careful execution. There is another and alphabetical catalogue of this part of the library in MS., as there is also of the collection of MSS. By the library statutes, access to the reading-room is restricted to graduates, and of them to such only as shall take the prescribed oath. But the enacting words, whilst they expressly exclude undergraduates, do not, in direct terms, exclude non-members of the University.³ The heads have accordingly given them, in practice, a liberal interpretation. No books are lent from this library; but a special lending collection has been provided for the undergraduates. It contains about 3000 well-selected volumes, and has worked advantageously.

Dublin has another library, strictly public in character, Archbishop Marsh's which has rendered eminent service to learning, though it is of small extent, and has narrow funds. Founded by Archbishop Marsh, about 1694, it was incorporated by act of parliament in 1707, and endowed by the founder's will in 1713. Lapse of time, and its results, which, in so many cases, have largely enhanced the value of endowments, has here seriously diminished what was formerly a fair maintenance fund. The library includes Bishop Stillingfleet's collection,⁴ another collection formed by its first librarian, and a series of nearly 3000 volumes, given by Bishop Stearne, together with some minor donations, nearly all of which accrued during the last century. The present number of volumes is about 18,000 printed, and 193 manuscript. Of late years Marsh's Library has been under excellent officers, and is very freely accessible, but it has long been starved for want of means to keep pace in any degree with the growth of literature. Whilst, on the other hand, the Library of the King's Inns, Dublin, which has always been conspicuous for its restrictive character, has already received in money, from the Consolidated Fund, L.8780; and, in money's worth, from authors and publishers, a further sum of nearly L.10,000, without any *public* equivalent whatever. The naïve remark of Mr Duhigg, the historian of the King's Inns, that "the genius of jobbing occasionally gives birth to a public-spirited establishment"⁵ could, by no ingenuity, have been more singularly misplaced.

The number of printed volumes in the King's Inns Library in January 1849 was 80,938, and that of MSS., 150.⁶ The Library of the Royal Dublin Society, founded in 1781, contains about 24,000 printed volumes, is eminently rich in the Dub-works on natural history, and has some valuable manuscripts, including the important collections of Harris, the historian of Ireland, which were purchased by Parliament of his widow for L.500, and committed to the Society's keeping. The Royal Irish Academy, founded in 1782, has a library of 10,500 volumes of printed books, and about 500 MSS., independently of the Betham collection on Irish archæology, acquired in 1851 (and not yet completely arranged), partly by a public subscription, and partly from the funds of the academy.⁷

Both this library and that of the Dublin Society have been largely aided by parliamentary grants. Both, therefore, are of right, and for some years past have been, in practice, accessible to the public, under proper regulations. But, within the last year or two, the disadvantages of thus separating these storehouses of learning, furnished at public cost, have become increasingly apparent; and powers have been judiciously taken, in framing the recent Act of Parliament for erecting an Irish National Gallery, to combine these collections with that of Archbishop Marsh, on obtaining the consent of their respective guardians, and

British
libraries.

¹ Parr, *Life of Ussher*, p. 102. The Ussher collection did not reach Trinity College until after the Restoration. Parr says that, whilst it was in Dublin Castle, "many of the books, and most of the best MSS. were stolen away."

libraries.

with all due precautions for the strict observance, both of that prelate's trust and of the proper associative purposes of the other bodies concerned. The new incorporation is to be designated "The Joint Trustees of the National Gallery of Ireland and of Marsh's Library."¹ By this union of so many scattered public collections a fine library of nearly 60,000 volumes—including a body of materials for Irish history of the greatest value—will be at once created. The duplicates may be made the basis of a good lending collection; and should the new institution be wisely worked under the rate-laying powers of the Irish Libraries Act, or under such modifications of those powers as may meet the special circumstances of the case, Dublin may soon possess a great public library worthy of the name. With the library of the King's Inns, Parliament will have to deal hereafter.

Free public
libraries in
the United
Kingdom,
established
under the
Acts of
1850-55.

Under the "Public Libraries Act" of 1850, or under the supplementary acts that have followed it, of which the "Irish Libraries Act" just referred to is one, free rate-supported libraries have already been established, or are now maintained, in the following cities and towns, namely,—Manchester, Liverpool, Salford, Boston, and Warrington (in *Lancashire*); Oxford; Cambridge; Westminster; Norwich; Winchester; Sheffield; Litchfield; Kidderminster (*Worcestershire*); Leamington (*Warwickshire*); Birkenhead (*Cheshire*); Ennis (*Clare*); and Dundalk (*Louth*). At Birmingham, Cheltenham, Exeter, Haslingden (*Lancashire*); Hull; in the metropolitan parishes of Islington and of St Mary-le-Bone; and in the city of London, propositions for the adoption of the act have been, for the present, negatived. By the corporations of Bristol, of Newcastle-on-Tyne, and of Preston (*Lancashire*), preliminary steps with a view to the ultimate adoption of the act have been initiated. Similar steps have also been taken in Aberdeen, at the instance of the present Lord Provost (John Webster, Esq., Advocate); and, we believe, in some smaller towns and in parishes in various parts of the United Kingdom.

Free library
of
Manchester

The city of Manchester was the first to establish a Public Library under the Act of 1850. Small collections of books, attached to museums of natural history, had previously been established (under Mr Ewart's "Museums Act" of 1845), by the town council of Warrington, in 1848; and by that of Salford in 1849 (at the recommendation of the late Mr Brotherton, M.P., whose attention had been called to the subject at the sittings of the "Select Committee on Public Libraries," which commenced its inquiries early in that year). But no power to levy rates, avowedly for the support of libraries, existed in the United Kingdom until 1850. The movement in Manchester was originated in the course of that year by Sir John Potter, then its mayor, and a public subscription was raised, which ultimately amounted to L.12,823. Out of this sum a building was purchased and adapted to its new purpose; and L.4156 was spent in books. The number of volumes so obtained was 18,028, and the number presented, by various donors, 3292. A poll of burgesses on the question of permanently maintaining the library by rate, under the Act, was taken 20th August 1852. The ayes were 3962, and the noes 40. The library was transferred to the Corporation, as an inalienable public institution, on the 2d September following, and was then opened as a consulting library to all comers (without any recommendation, or other preliminary); and as a lending library, to all persons producing a sufficient voucher of responsibility. It was the first library in the kingdom which offered these facilities; and during the first four years of its

British
libraries.

working, it has issued to readers and to borrowers, collectively, 584,792 volumes. During the same period, 11,255 volumes were added to the library, partly by purchase and partly by gift. Of the aggregate issue above mentioned, 322,103 volumes were lent to borrowers, and all the uncompensated loss which has fallen on the Corporation in consequence of this unprecedented freedom of circulation,—independently, of course, of fair wear and tear,—will be fully covered by a sum of 25s. The increased library rate of one penny in the pound will produce, in Manchester, L.4000 a-year, part of which sum will shortly be applied to the establishment of branch lending collections in other parts of that city. The total sum hitherto raised by rate amounts but to L.7485. The total contents of the library, in October 1856, were 32,573 volumes; the classification of which is as follows:—I. *Theology*, 1062; II. *Philosophy*, 421; III. *History*, 11,371; IV. *Politics*, 6830; V. *Sciences and Arts*, 2885; VI. *Literature and Polygraphy*, 10,004. Thus, it will be seen, 18,000 volumes out of 32,000 are either historical or political. This preference has been deliberately given, for the reason, that the selection of two or three principal departments of literature, as the main characteristic of the library, will enable the city council, in course of time, to make the collection one of the highest class and value, as respects those departments; whilst, on the other hand, the formation of an encyclopædical library, of equal value in all departments, would have been an aim too wide to be thoroughly attained. The library is frequented by *all* classes of the community, from those of least, up to those of greatest education. Merchant and artizan, mill-worker and clergyman, may be seen reading at the same tables; and as this (in Great Britain) is one of the most novel, so will it, in its ultimate issues, prove to have been one of the most pregnant results of rate-supported libraries, maintained by the payments of all classes, for the permanent use, the mental recreation, and the spiritual elevation of them all.

Liverpool, though second in the start, bids fair to be, in some respects, first at the goal. Its Free Library was established under a special Act,² which provided alike for the library, for the noble museum of natural history, bequeathed to the town by the late Earl of Derby, and for its botanical gardens. A sum of L.1400 was subscribed (for the purchase of books); the further sum of L.21,846 has been voted by the town council. This library, under regulations copied from those of Manchester, was publicly opened on the 18th October 1852, with a collection for use within the building, of 11,877 volumes; and, on the 18th October 1853, with two branch collections for the loan of books, in the northern and southern districts of the town, containing, together, about 2000 volumes. The reference collection has now increased to 21,020 volumes, and the two lending collections to 13,254 volumes, making an aggregate of 34,274 volumes. The total issues from the former have been 526,801, and from the latter, 364,347 volumes. Out of the issue to borrowers, but four books have been lost without replacement by the losers. As to the Reference Library, "the conduct of the readers," says the last Report, "and the care taken of the books, have been beyond all praise. Many of the artisans have expressed their gratitude and high appreciation of the privilege of consulting the valuable works in their various departments, more especially in ship-building, . . . cabinet and iron-work, and in various branches of practical science."³

This great success has necessitated the erection of a new and large building. The town council, early in 1856, ad-

libraries.

vertised for designs for such an edifice, and a collection of drawings, or sketches, from not fewer than 115 architects, was sent in. A second competition by 16 selected architects was invited, and the designs received were exhibited in St George's Hall. But the assigned limit as to cost was greatly exceeded by those designers whose projects best pleased the eyes of the committee. Great difference of opinion existed in the town council, and a third series of plans was about to be invited, when Mr William Brown, M.P. for South Lancashire, offered to take the whole charge of erecting the building upon himself. The plan which he is understood to have approved, cannot, it is stated, be carried out at a less cost than L.25,000. The first stone of the new structure is to be laid in April 1857.

Salford, which had continued to increase the small but useful reference collection attached to its excellent museum, opened its Free Lending Library in May 1854. The former contained, in November 1856, 12,603 volumes, and the latter 5952 volumes. The aggregate issues from both collections up to the date last named, amount to 476,825 volumes. The working of the library has been so satisfactory that a large expenditure has been incurred to increase the accommodation for readers, as well as that allotted to the museum. A total sum of L.7942 has been raised by subscription, for books and building purposes; and a further amount, somewhat exceeding L.6000, has been raised by rate, or voted by the town council. Even in the small town of Bolton, a sum of L.3195 has been raised by subscription, and a further sum of L.1500 by rate; a library of 15,000 volumes has been formed, partly for reference and partly for circulation; and the aggregate issues in three years have exceeded 285,000 volumes.

In the cities and towns of the S. and E. of England the working of the Library Acts has been too recent to afford results similar to those of which we have thus given an abstract for some of the towns of the N. But the experience of all, so far as it has extended, is highly satisfactory. There is, however, one point, more especially affecting the southern and eastern towns, which claims brief notice, inasmuch as it possesses practical and present interest. We refer to those few existing town libraries of ancient foundation, several of which might usefully be made the ground-work, and others the adjuncts, of free libraries supported by rate.

Ancient
town lib-
raries in
England.

In every instance, we believe, save one, these old libraries have fallen into neglect. Ipswich has a small collection which dates from 1580. In Norwich a public library was founded in 1608, and was afterwards much augmented by several benefactions.¹ In Bristol another was founded by Robert Redwood in 1615.² In Manchester, Humphrey Chetham, an eminent clothier, founded a library in 1653, and gave it, by his last will, a considerable endowment. A century later, Dr Shepherd, the biographer of Poggio Bracciolini, founded a town library at Preston. There are other small town libraries which cannot here be enumerated. Parochial libraries—of more than a hundred of which we have before us a chronological list—must also be passed over, with the bare remark that a great many of the latter were intended more especially for the use of the clergy, as parsonic heir-looms, so to speak; and that it was with a view to the preservation of these, for succeeding incumbents, that the Act of the 7th Anne, c. 14 (*An Act for the better preservation of Parochial Libraries in that part of Great Britain called England*), was passed in 1709.³

Parochial
libraries.

Both at Bristol and Norwich, the intentions of the founders have been utterly set aside by the unwarrantable trans-

fer of these city libraries to private societies, composed of shareholders and subscribers. But, in both instances, a vote of the municipal councils will suffice to restore them to their proper purpose. Neither possesses any present maintenance fund; both contain valuable books, and will make excellent foundation-stones for free libraries. At Preston the Corporation is already prepared to take this step. The case of Manchester is peculiar. Chetham's Library is the only town library of the seventeenth century which possesses a serviceable endowment, but even here the amount and efficiency of it have been seriously impaired, partly by reason of the subsisting connection between the library fund and that of the school of the same founder,—a school which has been productive of great good to the district, but which, to some extent, has thriven by impoverishing its neighbour,—and partly by reason of large expenditure on the restoration of the curious old baronial hall, of which both library and school are the occupants. This library possesses 18,200 printed volumes, and 137 manuscripts. It is rich in historical works (up to the middle of the last century, indeed, it is a fine collection); but its good old books lack those good new books without which they lose half their proper value. There is, however, some reason to hope that the precedent about to be set in Dublin will have its due influence in Lancashire, as well as in Norfolk and Gloucestershire.

(2.) FOREIGN LIBRARIES.

Having described the principal libraries of Great Britain and Ireland, we shall now proceed to those of foreign countries, and, in particular, endeavour to give some account of the principal collections in France, Spain, Italy, Germany, Holland, Belgium, Switzerland, Poland, Russia, Denmark, and Sweden. This account, however, must necessarily be brief and imperfect; for, owing to the magnitude of the subject, the space we can devote to the whole would scarcely be sufficient for an adequate description of the treasures contained in the Vatican and in the Imperial Library at Paris.

I. FRANCE.

The libraries of France may be divided into those of the capital, and those of the departments. The principal libraries of the capital are,—the Imperial Library, the Mazarine Library, the Library of the Arsenal, the Library of St Geneviève, the Library of the Sorbonne, the City Library, and the Libraries of the Senate, the Legislative Body, the Council of State, the Institute, and the Louvre. The libraries of the departments are 338 in number, exclusively of those which are specially annexed to learned bodies, to establishments of public utility, to colleges, and other institutions.

The Imperial Library at Paris is justly considered as the finest in Europe. It was commenced under the reign of King John, who possessed only 20 volumes; but the number was so increased by his successor, Charles V., who constructed a library in one of the towers of the Louvre, that, at his death in 1380, they amounted (according to Le Prince)⁴ to 910 volumes, several of them superbly illuminated by John of Bruges, the best artist in miniatures of that time. This precious collection was nearly destroyed during the troubles in the reign of Charles VII.; but what remained was recovered and greatly improved by Charles VIII., who added to it the choice books—still to be identified by the curious

But compare Van Praet's edition of the *Inventaire des livres du Roy nostre Sire, estans en son Chastel du Louvre*, which was drawn up by Gilles Mallet in 1373. The original is still visible in the Imperial Library (Fonds de Colbert, No. 83).

French
libraries.

visitor—which he carried off to France, after the conquest of Naples. Francis I. united it in 1544 with that of Fontainebleau, which had been enriched by valuable Greek manuscripts brought from the East. Henri IV. was also a munificent benefactor. He appointed the celebrated historian De Thou to be keeper; brought the Royal Library back to Paris, after an absence of nearly a century (it had been removed to Blois before its transfer to Fontainebleau); and added to it the fine collection of MSS.—more than 800 in number, and chiefly Greek—which had been formed by Catherine de Medicis. From this period the Royal Library continued to receive constant accessions. In 1684 it possessed 50,547 volumes; at the death of Louis XIV., upwards of 70,000; in 1775 it amounted to 150,000; and by 1790 it had increased to about 200,000. Then came the enormous, and for a long time almost chaotic accessions which accrued from the revolutionary confiscations. At present it contains about 815,000 printed volumes, and 84,000 manuscripts.¹

In 1667, Louis XIV., having ordered all the medals and curiosities contained in the royal residences to be collected together, caused them to be deposited in this library. Learned antiquarians, sent into foreign countries, augmented this collection; rare and precious objects were successively acquired; and the library at present possesses the richest and most varied collection that exists in Europe. The cabinet of engravings, also founded by Louis XIV., is composed of paintings on vellum, drawings, and an immense collection of prints, from the discovery of engraving to the present time. It contains more than 1,500,000, arranged in about 12,000 volumes and portfolios. In these numbers is included a noble series of portraits, exceeding 60,000, arranged, as far as possible, in chronological order. A second and still larger collection of portraits, formed by the Debures,—nearly 67,000 in number—has been recently purchased, and arranged in alphabetical order. Large selections of prints are constantly exhibited to all comers, under glass.

Organiza-
tion of the
Imperial
library.

The Imperial Library is at present divided into the following departments, viz.,—1st, Printed Books; 2d, Manuscripts, Charters, and Deeds; 3d, Coins, Medals, Engraved Stones, and other antique monuments; 4th, Engravings; 5th, Maps, Charts, and Plans. These five departments form five distinct establishments, which, by their importance and the richness of their treasures, exceed everything of the kind that is, as yet, to be found in other countries. A decree of 1556, which fell, or partially fell, into desuetude during the troubles of the Fronde, but was renewed in 1689, imposed on publishers the obligation of furnishing to the Library of the King, copies of all works printed with copy-right; and each copy was required to be bound. At present the law prescribes the deposit of copies of all books (as well as maps and engravings) printed; but the other condition is dispensed with.

The additions from the Vatican Library, selected by the French commissioners in 1797, were particularly valuable, amounting to 501 manuscripts. Of these, 20 were Hebrew; 40 Syriac; 19 Coptic; 11 Chinese; 133 Greek, amongst which was the celebrated *Codex Vaticanus* of the Septuagint; 176 Latin, including the famous Virgil, Terence, Horace, Cæsar, Plautus, and other ancient classical manuscripts; besides many other manuscripts illustrative of the

history of the ninth and tenth centuries. Numerous manuscripts in modern languages were also seized in virtue of the compulsory treaty of Tolentino, particularly the *Commedia* of Dante, transcribed by Boccaccio, the *Arcadia* of Sannazaro, Michael Angelo's *Letters*, and also those of Henry VIII. and Anne Boleyn; besides 136 early printed books, 13 Etruscan vases, and 737 ancient coins. To these were added the manuscripts and early printed books collected by the French in other parts of Europe, to which their victorious eagles had penetrated. But the events of 1814 and 1815 were followed by a large restitution of the literary treasures, as well as of the works of art, acquired by right, or rather by abuse, of conquest. Of the contents of this magnificent collection,—named successively *Bibliothèque du Roi*, *Royale*, *Nationale*, and *Impériale*,—it would far exceed our limits to give any details, or even to enumerate the choicest articles. Of books printed on vellum, it contains at once the finest and most extensive collection in the world.² Dr Dibdin, who visited the library in 1821, has devoted a considerable portion of the second volume of his *Bibliographical Tour* to a description of some of the chief literary and artistic treasures accumulated in this library, accompanied with numerous illustrations selected from some of the most precious manuscripts. Excepting on Sundays and holidays, the Imperial Library is open daily, from ten until three o'clock. Every book is brought that can be found; and literary men of known respectability are permitted to take books to their own residences.

French
libraries.

Hitherto there has been no complete catalogue of this vast collection. That of Labbe, printed in 1653, in 4to, treats of some manuscripts, which are divided into historical and chronological, biblical and theological, epistolary and diplomatic, technical and philological. Anicet Melot's catalogue of the manuscripts in the Royal Library was printed at Paris, 1739–1744, in 4 volumes folio. The first volume contains the Oriental manuscripts; the second the Greek manuscripts; the third and fourth comprise those in the Latin language. Besides these, the collection has furnished the materials for a work, published in successive volumes, by the Academy of Inscriptions, under the title of *Notices et Extraits des Manuscrits de la Bibliothèque du Roi* (or *Nationale*) et autres Bibliothèques. The 1st volume is dated 1787, the 17th, 1851, in 4to. This, however, is rather a collection of dissertations, and rescriptions of particular manuscripts, than a descriptive catalogue. The French manuscripts are described with great accuracy by M. Paulin Paris, in his work, *Les Manuscrits Français de la Bibliothèque du Roi*, Paris, 1836–1848, 7 vols. 8vo.

Of the printed books in the then Royal Library, there appeared a catalogue compiled by the Abbés Sallier, Boudot, Capperonnier, and others, in 6 vols. folio, Paris, 1739–1750. It contains the classes Theology, Belles-Lettres, and part of Jurisprudence. After the lapse of a century, the want of a general catalogue having been felt, the deficiency is about to be supplied, by direction of the present Emperor. The task has been undertaken with energy, and carried on with an amount of success worthy of the collections which have accumulated. The new catalogue commences with the class of French History. It is printed in large 4to, in double columns, the books chronologically arranged under the different reigns or periods of govern-

¹ These numbers are based on the official return made in 1850, by General De La Hitte (then Minister of the Interior), to Lord Normanby, in consequence of an application from the Foreign Office (at the instance of Mr Ewart's Committee on Public Libraries). This return says, "700,000 printed volumes, and 500,000 tracts." The latter may be estimated as at least equal to 5,000 volumes. The yearly increment from copy-tax alone, is further stated to be 12,000 volumes. The number of MSS. is reported at "8 707 volumes, and 300,000 charters," &c. M. Grün ("Archiviste de la Couronne"), in his excellent *Dictionnaire de l'Administration Française* (1854), says, "More than 800,000 printed books, and 80,000 MSS."

² The number of books printed on vellum, contained in the Royal Library at Paris, amounts to 1467, exclusively of those restored in 1814 and 1815. The total number of books of this sort extant does not exceed 2700. Lord Spencer's collection, which is the richest in this country, contains only 108. (Van Praet, *Catalogue des Livres imprimés sur Vellin de la Bibliothèque du Roi*, Paris, 1822, in 6 vols. 8vo.)

French
libraries.

ment. The three volumes already published, 1855-56, according to an enumeration prefixed, include 45,729 articles. The fourth volume, which completes the class, is in the press, and will be followed by other classes or divisions. The manner in which the work is executed is worthy of imitation by the Trustees of the British Museum, and of all other great national libraries.

Mazarine
library.

This library was founded by Cardinal Mazarine. The formation of it was intrusted to the learned Gabriel Naudé, who, having first selected all that suited his purpose in the booksellers' shops in Paris, travelled into Holland, Italy, Germany, and England, where the letters of recommendation of which he was the bearer enabled him to collect many very rare and curious works. In 1648 this collection consisted of 40,000 volumes, and was already a public library by its owner's liberality; though that of the king did not become one until 1737. In 1660, Cardinal Mazarine, by his will, bequeathed it to the college which he founded, and which, until the epoch of the Revolution, bore the name of the founder. At present it contains about 132,000 printed volumes, and nearly 3000 manuscripts. It is remarkable for a great number of collections containing detached pieces and tracts, which date as far back as the fifteenth century, and exist nowhere else; nor has any other library so complete a body of the ancient books of law, theology, medicine, and the physical and mathematical sciences. It also possesses a most precious collection of the Lutheran or Protestant authors. The Mazarine Library is habitually frequented by from twenty to eighty readers, according to the season of the year. It is supported by an annual grant of about L.1300, provided for in the budget.¹

Library of
the Arse-
nal.

This library, founded by the Marquis of Paulmy, formerly ambassador of France in Poland, was, in 1781, acquired by the Count d'Artois, who conjoined with it a portion of the Library of the Duke of La Vallière. It consists of more than 202,000 printed volumes, and about 6000 manuscripts. It possesses the most complete collection extant of romances, since their origin in modern literature; of theatrical pieces, or dramas, from the epoch of the moralities and mysteries; and of French poetry since the commencement of the sixteenth century. It is less rich in other branches, but it has all works of chief importance, and, in particular, contains historical collections which are not to be found elsewhere. The Library of the Arsenal has always attracted the attention of the learned from all parts of Europe. It is constantly frequented by from forty to fifty readers, who there apply themselves to scientific and literary researches. The annual grant for its support was, in 1850, 36,000 francs, or L.1440.²

Library of
St Gene-
viève.

The foundation of this library dates from the year 1624, when Cardinal de Rochefoucauld, having reformed the community of Sainte-Geneviève, made it a present of 600 volumes of books. In 1687 the abbey is said to have had already 20,000 printed volumes, and 400 volumes of manuscripts. In 1710 Letellier, Archbishop of Rheims, bequeathed to it all his books.³ At the epoch of the Revolution, it possessed 80,000 printed volumes, and 2000 manuscripts; at present it contains nearly 180,000 volumes, and 3500 manuscripts. In it may be found the principal academical collections, and a complete set of Aldines. It is particularly rich in historical works; and its most remarkable manuscripts are Greek and Oriental. Its typographical collections of the fifteenth century are not more valuable for

their number than for the high state of preservation in which they are found. This fine library is daily frequented by upwards of 300 persons, including many students in the different faculties. It is supported by an annual grant from the public treasury of 75,200 francs, or upwards of L.3000;⁴ and has recently been placed in a new and handsome edifice, erected for its accommodation. The reading-room of this building is the most convenient and capacious one in Paris, as the library itself is the most frequented.

French
libraries.

The City Library is supported by grants from the funds of the municipal council. The foundation dates but from the beginning of the present century; Paris having lost its original City Library, by one of the incidental results of the Revolution. The first books for the new collection were obtained, however, in great measure, from the revolutionary confiscations; and were afterwards augmented by the exertions of the Prefect of the Seine, and of some of the municipal authorities. In 1827 it had grown to 45,000 volumes, and now possesses at least 55,000. The Library of the Palace of the Luxembourg (formerly that of the Chamber of Peers), contains nearly 40,000 volumes, and has allotted to it a sum of 10,000 francs for the purchase of books and to defray the expense of binding. The University Library, which is placed in the buildings of the Sorbonne, consists of 40,000 printed volumes, and 1000 MSS. It is very useful to the students of the different faculties, who frequent it in the intervals between the lectures. It expends annually a sum of about L.1100.⁵

Other pub-
lic libraries
of Paris.

The nucleus of the present Library of the Institute was the old City Library (*Bibliothèque de la Ville*), founded by the eminent magistrate, M. Morieau, who died in 1759, bequeathing to the municipality his collection of 14,000 printed volumes, and 2000 MSS., on condition that it should be publicly accessible. To this gift a liberal addition was made by M. Bonamy, the first and eminently learned librarian. The Library of the Institute having been plundered during the first Revolution, that of the City was transferred to it, by way of compensation. At present this excellent and useful collection amounts to more than 80,000 volumes. It exhibits the best possible selection of the principal works in all the important branches of human knowledge; and it may be truly said that it is kept up to the actual state of science and learning. In the acquisitions which are made, the object is not to search for rare editions, but to obtain such as possess some peculiar merit. Academical collections of all kinds and of all countries, magazines and journals of science and literature in all languages, are to be found here in greater number than anywhere else. This collection is reserved for the members of the five academies of which the Institute is composed; but all strangers presented by them are admitted, and it is *de facto* public.

Library of
the Insti-
tute.

The provincial libraries of France, as they are chiefly supported at the expense of the different cities, are naturally placed under the immediate direction of the mayors and municipal councils; but they are not the less on that account under the superintendence of the superior authority of the Minister of Public Instruction. Their number, as already stated, amounts to 338, exclusively of those attached to societies, colleges, and other institutions. Amongst the most considerable are those of Strasburg, which, at the date of the latest official returns, contained about 180,000 printed volumes, and 1589 MS. volumes; Lyons (120,000 printed, 1518 MSS.); Rouen (110,000 printed, 2355

Provincial
libraries.

¹ General De La Hitte to Lord Normanby, 18th March 1850 (App. to *Report from Select Committee on Public Libraries*, 1850), pp. 176-259. Of the original formation of this library, some curious notices have been collected in the 6th volume of that valuable work of M. Paulin Paris, which we have mentioned on the preceding page.

² According to the notice of Letellier, by Weiss, published in the *Biographie Universelle* (vol. xxiv., pp. 338-339), his bequest was of no less than 50,000 volumes. There is an excellent catalogue of the collection by Nicolas Clement (*Bibliotheca Telleriana*, 1693, folio), to which the Archbishop himself prefixed an account of its formation.

³ *Projet de Budget révisé des Dépenses de l'Exercice* 1850 (Paris, 1849), cxxvii. Comp. De Bougy, *Histoire de la Bibliothèque Sainte Geneviève* (1847), p. 149.

⁴ Ibid.

⁵ Ibid.

Foreign MSS.; Troyes (about 100,000 printed, 3000 MSS.); Aix (95,000 printed, 1062 MSS.); Grenoble and Besançon (each containing about 80,000 printed volumes, and 1500 MSS.); Avignon (60,000 printed, 1200 MSS.); Versailles (55,924 printed, 115 MSS.); Amiens (53,000 printed, 600 MSS.); Marseilles (51,219 printed, 1335 MSS.); Toulouse, Dijon, and Nismes (each with about 50,000 printed volumes, and of MSS., 700, 500, and 207 respectively); Nantes (45,000 printed, 187 MSS.); Caen (40,107 printed, 226 MSS.); Le Mans (40,000 printed, 700 MSS.); Rennes (40,000 printed, 220 MSS.); Arras (36,772 printed, 1137 MSS.); Douay (36,500 printed, 970 MSS.); Chaumont (35,000 printed, 160 MSS.); Colmar (34,859 printed, 481 MSS.); Cambrai (33,133 printed, 1254 MSS.); Orleans (33,000 printed, 486 MSS.); Rheims, Soissons, Nancy, Beaune, and Montpellier (each with about 30,000 volumes of printed books; and with 1300, 293, 265, 160, and 68 volumes of MSS. respectively.¹ The MS. collections of Troyes (a library founded expressly for public use, as early as 1651), Grenoble, Besançon, Aix, Rouen, Nantes, Rennes, and even those of the comparatively small libraries of Montpellier and Auxerre, are rich mines of lore never yet thoroughly explored. The catalogue of the manuscripts in the Library of Lyons, 1518 in number, is one of the most interesting which has issued from the French press (*Paris et Lyon*, 1812, in 3 vols. 8vo). The preliminary disquisition contains notices of the former libraries of Lyons; the historical essay on manuscripts contains an account of the materials anciently used in writing; the biography of writers who have treated of the subject, though brief, is worthy of attention; and the manuscripts are classed and described with much judgment and learning.² At Rouen is the remarkable missal, written by a Benedictine monk, who died in 1714, the work of thirty years; also, St Guthlac's famous missal of the eleventh century, and the still earlier *Benedictionarius*.³

In the extensive series published at the expense of the French government, *Documents sur l'Histoire de France*, we find the commencement (in 2 thick volumes 4to), of a *Catalogue Général des Manuscrits des Bibliothèques Publiques des Départements*, under the direction of the Minister of Public Instruction; Paris, 1849-1855, 2 vols. 4to.

The small Library of Vire,—the antique and craggy little capital of the Bocage of Normandy,—merits at least a word of notice, on account of the singular circumstances which attended its formation. The founder, Thomas Tyrrel, a Frenchman by birth, was an Englishman by naturalization as well as by predilection. He formed his library in London, during a residence of more than twenty years, and bequeathed it to Vire, his birthplace, by his last will. There it remained in cases untouched for nearly as long a period, when, by a lucky accident, it attracted attention, and was made the nucleus of a useful library.⁴

II. SPAIN.

Spanish The number of public libraries in Spain is greater than libraries. has commonly been supposed; nor have the science and literature of that country quite sunk to such a state of depression as some have been pleased to represent. Its principal library is the *Biblioteca Real*, at Madrid, which is

now lodged in an edifice, once the mansion of the Alcanices family, on the Plaza del Oriente. It is open to all comers, as far at least as the printed books are concerned. The reading-tables are placed in three spacious apartments, corresponding to as many sides of the edifice, which is built round a court, with a fine staircase in the centre; in the middle of these rooms are rows of tables provided with writing materials and chairs; and against the walls are the book-shelves, numbered and tastefully ornamented. The catalogues are kept in a small room apart, where there are two or three persons in attendance to answer the inquiries of the stranger, and to furnish him with the number and shelf where any particular work may be found. The service of the library is excellent. The Royal Library contains about 200,000 printed volumes, and from 2000 to 3000 manuscripts, amongst which are many valuable Greek, Latin, and Arabic manuscripts, and inedited works, chiefly Spanish. The *Monetario*, or cabinet of medals, is arranged in an elegant apartment, and contains an unrivalled collection of Celtic, Phœnician, Carthaginian, Greek, Roman, Gothic, Arabic, and modern coins and medals, in excellent preservation. "Le cabinet des médailles de Madrid," says M. Faure, "est sans doute le plus remarquable de l'Europe. Tandis que Paris, qui l'emporte si incontestablement sur la capitale des Espagnes par les monumens des arts et de l'antiquité, n'a que cent mille médailles dans sa collection, il y en a cent quatre-vingt-trois mille dans celle de Madrid: cent cinquante mille sont classées dans l'ordre le plus parfait; trente-trois mille seulement restent à classer. Ces preuves matérielles du passage des Celtes, des Tyriens ou Phéniciens, des Carthaginois, des Romains, des Vandales, des Suèves, des Alains, des Goths, des Maures sur cette malheureuse terre qu'ils se sont arrachée les uns aux autres, réconcile avec les Espagnols, dont on a d'ailleurs tant d'occasions d'accuser l'indifférence. On trouve dans cette collection précieuse de quoi applaudir au zèle de ceux qui l'ont formée et de ceux qui l'entretiennent avec tant de soin."⁵ A more recent traveller, speaking of the *Biblioteca Real*, says, "It is one of many institutions which awaken the admiration of the stranger in Spain, as being at variance with the pervading decay."⁶ Mr Ford, however, tells us that "good modern books are here, as in most other Spanish libraries, the thing needful."⁷ The only catalogue that has been printed is volume first of the Greek manuscripts, by D. Juan Yriarte (Madrid, 1769, folio); and no second volume has ever appeared.

There is another extensive but chaotic library, "one of the many treasures buried in Spanish napkins," where, according to Mr Ford, "are left to the worms, some 100,000 volumes," . . . including the "secret correspondence of Gondomar, during his embassy to England, with the identical letters received from the lords, ladies, and gentlemen, whom he bribed for Philip III., as Barillon did afterwards for Louis XIV. His letters, likewise, on lighter social subjects are extant. This buried mine of the Shakspearian period, which clamours for a Collier, lies unexplored in the private library of the Crown."⁸

The convent of the Escorial, situate upon the southern declivity of the Guadarrama chain, about half way up the mountain, owes its existence to a vow made by Philip II. during the crisis of the battle of Saint-Quentin in 1557. It

¹ Returns addressed by the prefects of the several departments to the French Ministry of Public Instruction, in the years 1853 and 1854, and of which an epitome was published in the *Journal Général de l'Instruction Publique* of the 15th Nov. 1854.

Foreign
libraries.

derives its name from San Lorenzo del Escorial,¹ to whom it was dedicated, and has been often described. At present we have only to do with the literary treasures contained in this magnificent edifice. The library is 195 feet in length, 32 in breadth, and 36 in height. Its vaulted ceiling is ornamented with arabesques and colossal figures, by Pellegrino Tibaldi; the book-cases, of cedar, are beautifully carved, with painting in fresco, by Bartolomeo Carducci, emblematical of the several divisions of the works ranged upon the shelves. Of the contents of this library no trustworthy account is extant; it has been repeatedly said to contain 120,000 printed volumes (unquestionably a gross exaggeration; it is probable that at no time has it contained more than one-third of that number), and between 4000 and 5000 manuscripts, of which 567 are Greek, 67 Hebrew, and 1800 Arabic. The Arabic manuscripts were originally much more numerous,² but a large proportion of them was consumed by the fire which, in 1671, destroyed a great part of the library, and all that remains is the number just stated. Besides these, which are extremely curious, there are other manuscripts of great rarity and value, particularly one, *Codex Aureus*, containing the Four Gospels, written on 160 leaves of vellum, in gold letters, and supposed to be of the tenth century; a treatise by St Augustin, *De Baptismo Parvulorum*, said, by Spanish writers, to be in his own handwriting; the original works of St Teresa; and a parchment roll containing an original Greek manuscript by St Basil. The books are placed, with their backs to the wall, so that the edges of the leaves are turned outwards, and the titles of the works written thereon. This was the practice of Arias Montanus (who bequeathed his Greek, Arabic, and Hebrew MSS. to the Escorial, and his printed books to Seville); and the same absurd method has continued to be followed.³ There is no printed catalogue of the books; Casiri's very inaccurate catalogue includes only the Arabic manuscripts rescued from the conflagration of 1671, with a few others subsequently acquired. This catalogue, however, is in one respect valuable, inasmuch as each manuscript is not only enumerated, but its age and the author's name, when known, are also given, together with occasional extracts both in the original Arabic and in the Latin language.⁴

An excellent catalogue of the Greek MSS. by Miller, was printed at the expense of the French government, in 1848; for, to the honour of France, under all its changes of polity and administration, the promotion of learning is uniformly regarded as one of the public duties of a government, whatever its party complexion, and alike whether the political barometer may stand at "stormy," or at "set fair."

The number of provincial libraries in Spain is considerable; but (like too many of the libraries themselves) unprogressive. There is no official account of them of later date than 1835, when the more extensive and important were then stated to be those of Toledo (30,000

printed books), Salamanca (24,000, with 1500 MSS.), Santiago University at Corunna (17,307, with 41 MSS.), and Valladolid (13,250). At Malaga, Peruel, Murcia, Lugo, Cervero, Oviedo, Palma, and some other places, not to mention the library of the Asturian Institute, and that of the Junta of Commerce at Corunna,⁵ are collections of books varying from 3000 or 4000 to between 9000 and 10,000 volumes each.

Elsewhere than in Spain, the Columbian library at Seville would surely have grown into a very cynosure of book-lovers. At one time, it was so choice a collection as to be worthy of the great name it bears; but (*cosa de España*) the *tinea* and the *blattæ* had it so long to themselves, that they quite ruined many of its treasures, although it still possesses about 18,000 volumes; and, amongst them, a precious MS. in which Columbus tried to satisfy the Inquisition that his discovery had been scripturally predicted; it has also some books that were his cabin companions, and bear his MS. notes.⁶

Foreign
libraries.

III. ITALY.

Amongst the libraries of Italy, that of the Vatican, at Vatican Rome, stands pre-eminent, not more for the grandeur and magnificence of its habitation, than for the inestimable treasures with which it is enriched. Pope Nicholas V. (1447), learned himself, and a distinguished patron of letters, is justly considered as the founder of the Vatican Library; for of the collections of his predecessors little remained when he ascended the papal throne, the books having been either lost or destroyed by the frequent removals from Rome to Avignon, and from Avignon to Rome. This pontiff added above 5000 manuscripts to the fragments of the original collection, placing all in the Vatican; and Calixtus III. is said to have enriched it with many volumes saved from the libraries of Constantinople, when that city fell into the hands of the Ottomans. The collection, however, suffered an almost total dispersion at the sacking of Rome, by the Duke of Bourbon, in the year 1527. Pope Sixtus V., a man of learning, and a zealous patron of the arts, rebuilt the library in 1588, and considerably augmented the collection. From this period it continued to increase in steady progression, receiving additions, almost every year, sometimes even of whole libraries, owing not only to the favour of the pontiffs and various princes, but also to the well-directed zeal of its librarians, many of whom have been men of eminent talents as well as of high rank and extensive influence. Under Gregory XV. an important addition was made by Maximilian, Duke of Bavaria, who, yielding to urgent entreaties and cunning devices, presented to that pontiff the old Library of Heidelberg, belonging to the Elector Palatine, which had been part of the plunder seized by Tilly at the capture of

¹ *Escorial* is formed from the Spanish word *escoria*, signifying *dross*. It is commonly applied to all places where there are old or exhausted mines.

² In a fortress belonging to the Emperor of Morocco, there were found, it is said, 4000 Arabic manuscripts, which were carried to Paris for sale; but not being prized in that capital, they were transported to Madrid, where about 3000, including the most valuable, were selected for the Library of the Escorial by order of Philip II. But we do not vouch for the story.

³ It is not a little singular, that in the return of the "Public Libraries and Archives of Spain," made to Lord Palmerston by Mr Villiers, and printed in the Appendix to the *Report on the British Museum* (p. 511, *et seq.*), no notice whatever is taken of the Library of the Escorial; whilst the regulations of a provincial library (that of the Junta of Commerce at Corunna) are inserted at full length.

⁴ The Library of the Escorial has always been difficult of access. Probably no library, containing such treasures, ever rendered so small service to literature; and none, perhaps, has suffered more severe losses, not alone by calamity, like fire, but from sheer plunder. When Los Santos wrote his *Description breve del Monasterio del Escorial* (1657), it certainly contained 18,000 volumes. It received considerable accessions, but most of them were antecedent to the destructive fire of 1761. Very soon after that event, Beaumarchais visited the library, and his keen observation detected an agency that was to prove more fatally obstructive of the growth of a great library than fire could be. The works of all our "modern philosophers," he says, are prohibited, and not only all that they have written, but "all that they may hereafter write." (Letter to the Duke of La Vallière, Madrid, 24th Dec. 1764, published in the *Revue des Deux Mondes*.) About 1809 it was removed to Madrid, and when restored by Ferdinand VII., nearly 10,000 volumes, according to Mr Ford, lost their way. Mr Inglis saw it in 1830, and says that it did not then contain more than 24,000 volumes. (*Spain in 1830*, vol. i., p. 347.)

⁵ See Appendix to the *Report on the British Museum*, pp. 514, 515, *et seq.*

⁶ Ford, *ubi supra* (p. 176).

Foreign
libraries.

Heidelberg in 1622. Among other important additions that have a claim to notice are,—the greater part of the Library of Urbino, founded by Duke Federigo; a portion of the collection of the Benedictine monastery of Bobbio, composed chiefly of palimpsests; and the books and manuscripts of Christina, Queen of Sweden, comprising the treasures taken at Prague, Wurtzburg, and Bremen, by her father, Gustavus Adolphus. After her death at Rome, they came, by succession, to the family of Ottoboni. Pope Alexander VIII., as head of that family, in 1690, placed 1900 of the MSS. in one of the galleries of the Vatican, and gave it the appellation of *Bibliotheca Alexandrina*, in honour of the Queen, who had received the additional name of Alexandrina on abjuring the Lutheran religion. All the MSS. in the Vatican, anterior to the ninth century, and those with the choicest illuminations, to the number of about 500, were selected and conveyed to Paris in the year 1797, but the greater part were restored in 1815. Of the Palatine MSS., about 900 volumes, more than nine-tenths of them German, but among which were some early Greek MSS., were at length returned (in 1816) to the University of Heidelberg, where they now remain.¹

The magnificent library of the Vatican consists of three divisions or compartments, besides the vestibule; the anteroom, the double gallery, and the great saloon or hall. The vestibule contains Chinese works relating to geography and chronology, together with two columns bearing ancient inscriptions. The anteroom is appropriated to the two keepers of the library, and the secretaries, or interpreters, usually seven in number, who speak the principal languages of Europe, and who attend for the convenience of learned foreigners. In this apartment are also accommodated those engaged in translating from the Hebrew, Arabic, Syriac, Greek, and Latin languages; and it is open daily for the use of students, Sundays, Thursdays, and very numerous holidays excepted. Passing from the anteroom, the visitor enters a double gallery of 220 feet in length, on either side of which are arranged the Greek and Latin MSS. of the ancient Papal collection, which strangers at first conceive to be the whole library; but at its extremity there opens up, in almost interminable perspective, another gallery of about 1000 English feet in length.² As the visitor enters this gallery, or "great hall of the Vatican," he has on his right hand the Palatine and Urbino collections of MSS., and, beyond them, the general library of printed books; whilst, on his left, extend in succession the Oriental MSS.,³ the MSS. of Christina, the Ottoboni MSS., those bequeathed by the Marquis Capponi, and (last of all) the

Foreign
libraries.

choice collection of printed books on the fine arts, nearly 5000 in number, formed by Count Cicognara, and purchased by Leo XII. for L.4000. These galleries and apartments, all vaulted and painted with varied effect by painters of different eras and talents, constitute the receptacle of this noble library. The books are nearly all kept in close cases; so that in the Vatican the stranger seeks in vain for that imposing display of volumes which he may have seen and admired in other libraries. Their number has never been officially and precisely recorded; and such is the discrepancy of the various accounts, that the printed books, by some reckoned not to exceed 30,000* or 50,000 volumes, by others are stated at ten times these numbers. This monstrous discrepancy has been occasioned partly by the want of a catalogue, and partly also by the books being kept in close cases. Valery, whose statements in other similar matters we have found to be trustworthy, and who appears to have had some facilities of access and examination, estimated them, in 1840, at 80,000 volumes. We are not now inclined to reckon them as exceeding 100,000 volumes; as the collection is not increased, like many other great libraries, by extensive and systematic purchases. Of the manuscripts, the same author fixes the number at 24,000, namely, 5000 Greek, 16,000 Latin and Italian (these last only in small number), and 3000 in various Eastern languages. The official return of 1850 says 25,000 MSS.

But the importance of a library is not to be estimated by the mere number of volumes. The great value of the Vatican Library consists in its manuscripts. Those usually shown to visitors impress the mind with no ordinary ideas of their inestimable value and importance, and include some of the highest antiquity, such as the Virgil of the fourth or fifth century, written in uncial letters, and illuminated with most curious miniatures; a Terence equally ancient; another of the ninth century, illuminated with ancient masks; the celebrated Greek Bible of the sixth century (*Codex Vaticanus*), written in capital letters, according to the Septuagint version, and from which all the subsequent copies have been taken; and the Gospels of St Luke and St John written in the tenth century, and bound in ivory. There is also the palimpsest, containing the treatise of Cicero *De Republica*, discovered by Cardinal Angelo Mai, conjectured to be of the third century; and perhaps, in the form of books, this, and the Virgil, are the oldest manuscripts in existence. Amongst the rare manuscripts in this splendid collection may also be mentioned, several Hebrew, Syriac, Arabic, and Armenian Bibles; a very large Hebrew Bible⁴ formerly in the library of the

¹ *Serapeum* (1845), vol. vi., pp. 157-8. The best account of the transfer and subsequent fortunes of the Palatine collection—not the least curious episode in the remarkable history of the Vatican Library—may be found in Dr Anton Ruland's elaborate essay, entitled, *Zur Geschichte der alten nach Rom entführten Bibliothek zu Heidelberg*, which occupied several numbers of the *Serapeum* in 1856 (vol. xvii., pp. 185-191; and 193-235). The reader should also consult, besides the well-known work of Wilken (into whose hands the partial restitution of 1816 was made), Theiner's *Schenkung der Heidelberger Bibliothek . . . und ihre Versendung nach Rom; mit original Handschriften*, published at Munich in 1844; but, in reading this work of the worthy Oratorian priest, he will do well to have beside him the keenly critical articles which appeared in the *Serapeum* of the following year (vol. vi., pp. 1-11; 113-127; 129-159), from the pens of Dr Gessert (of Munich), and of Dr Bahr (of Heidelberg). Dr F. L. Hoffman has also contributed an interesting paper (including an early Palatine catalogue), towards the elucidation of a subject which has always had special attractions for bibliographers, in the same *Journal* for 1850, vol. xi., pp. 161-173; 177-188; 193-208). Allatius wrote in Italian a tract on the conveyance of the Palatine Library to Rome, under his direction, which tract was translated into Latin by Quade, and published at Gryphiswald, 1708, 4to. (Leonis Allatii, *Instructio de Bibliothecâ Palatinâ Romam transportandâ*.) The writer takes pride in the fact that not a leaf of the library was lost on the road.

² *Rome in the Nineteenth Century*, vol. ii., p. 383, Edinburgh, 1822, 8vo.

³ Of the Oriental MSS. there is a valuable catalogue by J. S. Assemani, *Bibliotheca Orientalis Clementino-Vaticana, Roma*, 1719-28, 3 vols. folio. It is continued by Angelo Mai, in the fifth and subsequent volumes of his *Nova Collectio Scriptorum Veterum*. In Montfaucon's *Bibliotheca Bibliothecarum Manuscriptorum nova*, Paris, 1739, 2 vols. folio, is given a catalogue of Queen Christina's manuscripts.

⁴ Sir George Head, writing of repeated visits made to the Vatican in 1840 and 1841, says roundly, "The reputed contents of the whole establishment amount to 30,000 printed books, and 23,580 MSS. (*Rome, a Tour of many days*, vol. iii., p. 231.) Mr Curzon, on the other hand, a writer versed in such subjects, and also writing of visits in 1840, says, "about 100,000 printed books, and about 36,000 MSS." (*Notes on Italian Libraries*, privately printed in *Miscellanies of the Philobiblon Society*, 1855, pp. 34, 35). The official return obtained by our Foreign Office in 1851, runs thus:—"The present number of printed volumes is about 100,000; of MSS., 25,000. The number of tracts or pamphlets is reported to be incalculable."

⁵ "They think it to be of great antiquity, but . . . it is of A.D., 1294." (Montfaucon, *Diarium Italicum*, c. xx.) This visit of Montfaucon was in 1698. The MSS. were then, he was told, "nearly 12,000 in number."

Foreign
libraries.

Dukes of Urbino, for which—though it is so ponderous as to require two men to carry it!—the Venetian Jews are said to have offered its weight in gold; a Greek manuscript containing the Acts of the Apostles, written in gold letters, and presented to Innocent VIII. by the Queen of Cyprus; a Missal written in 1118; another adorned with miniatures by Giulio Clovio, the scholar of Giulio Romano, and the finest miniature painter of his time; a large Breviary, ornamented with beautiful miniatures and presented to the library by Matthias Corvinus, King of Hungary; the *Annals of Baronius*, in 12 volumes, written with his own hand; several volumes of Ecclesiastical History, by the learned Onofrio Panvinio; a Martyrology, curious on account of its antiquity and its miniatures; a manuscript of Pliny, with fine miniatures of animals; a beautiful Dante adorned with exquisite paintings, begun by the Florentine school, and finished by Giulio Clovio; another Dante, the most precious that exists of the *Divina Commedia*, in the handwriting of Boccaccio, and sent by him to Petrarch, thus connecting the three great names of Italian Literature; also an autograph manuscript of the *Rinaldo* of Petrarch, with his corrections; and another autograph of Tasso, including a sketch of his *Gerusalemme Liberata*, written when nineteen years of age. To some English visitors, the most interesting volumes are the dedication copy, printed at London by Pynson, in 1521, on vellum, of Henry VIII.'s treatise against Luther, *Assertio Septem Sacramentorum adversus Mart. Lutherum*, with this distich in the king's autograph on the last page,—

"Anglorum rex Henricus, Leo Maxime, mittit
Hoc opus, et fidei testem et amicitiae;"—

(a work which obtained for that monarch his title of *Fidei Defensor*); and his Love Letters to Anne Boleyn, seventeen in number, nine in French, and eight in English, which have also found a place in this library. It is rich in early printed editions, and amongst those on vellum may be specified the Epistles of St Jerome, printed at Rome in 1468; Aulus Gellius, 1469; the Greek Bible of Aldus, 1518; one of four copies of the celebrated Polyglot Bible of Cardinal Ximenes, 1514–1517. This library possesses a very fine cabinet of medals, which was carried off by the French, but restored, after the events of 1814 and 1815. There is also attached to it a room filled with a fine collection of prints, to which admission can only be obtained by a particular order; and in another are deposited the secret archives of the Vatican, to which, of course, there is no admission at all. A cardinal is always nominal librarian. Of the difficult accessibility of this great storehouse, at almost all periods of its history, it were easy to adduce a long chain of testimony. Some years since, Cardinal Consalvi somewhat relaxed the prevailing restrictions, but the liberality scarcely survived its author. "The Papal government," writes Von Raumer, in 1839, "has returned to the old seclusion and exclusion."² "Of all the tombs in the world, the Vatican Library is the most impressive," says Mr Samuel Laing in 1842; . . . "Book-cases well stocked; no readers; no [accessible] catalogue."³ "The privilege of consulting books," says Sir George Head, a year or two later,

"is merely nominal, in consequence of the imperfect state of the catalogue; and, in point of fact, the multitudinous volumes on the shelves may be compared to a mine . . . whence only a few particular objects, considered as the staple curiosities of the region, . . . are extracted."⁴ Even the return to the inquiries of the Foreign Office, in 1851, after describing the authorized regulations as to access, adds, "There are few days in the year in which it is open to the public."⁵ In fine, there is ample evidence that this library has yet to be explored, and that an abundant harvest awaits those future inquirers who to the requisite skill may join inflexible perseverance and happy fortune.

The other libraries at Rome, of sufficient importance to deserve notice, are the Barberini collection, containing between 30,000 and 40,000 volumes of printed books, and about 7000 manuscripts. This collection was formerly open to the public, but has ceased to be so, "on account of extensive robberies which took place some years ago."⁶ (2.) The *Casanata* Library, bequeathed by Cardinal Casanate to the Dominican convent in the Piazza della Minerva, in 1700, together "with suitable funds to render it one of the first in Italy and Europe."⁷ It occupies magnificent apartments. According to the official return of Monsignore Barardi (1851), "the number of volumes exceeds 200,000," (not counting pamphlets, miscellaneous works, and plays, which exceed the number of 3000.) The accessibility of the library is liberal.⁸ (3.) The *Angelica* Library, founded by Angelo Rocca, and the first collection opened to the public in Rome (1604), containing 84,819 printed books, 2945 MSS., and 60,960 tracts (*opuscoli*).⁹ The number of persons frequenting it—no ticket of admission being requisite—is stated to be from 30 to 40 daily. It includes the collections of Pignoria, Holstenius, and Passionei. (4.) The *Alexandrine*, or "Sapienza" Library, founded by Alexander VII., also the founder of the library in the Chigi palace, (now, we believe, closed like the Barberini, save by special favour). It appears to contain about 80,000 printed volumes, and 3000 MSS. The reigning Pope has given permission, granted to no other library in Rome, for the keeping this library open to the public in the evening.¹¹ (5.) The *Corsini* Library, founded by Clement XII., occupies 8 rooms in the Corsini palace, and is stated to contain about 60,000 printed volumes, and 3000 MSS., with 60,000 engravings. Its manuscript collection is poor in classics, but abounds in documents illustrative of the history, both political and literary, of the sixteenth and seventeenth centuries.¹² (6.) The Franciscan, or *Aracelitana* Library, containing, according to Sir George Head (1841), 18,000 volumes;¹³ but according to the Foreign Office Returns (1851), though "despoiled of the greater part of its most valuable works after the French invasion, it has still from 40,000 to 50,000 volumes."¹⁴ (7.) The *Lancisiana* Library, founded in 1721, and placed in the Hospital of the Holy Ghost, with "from 30,000 to 40,000 volumes."¹⁵ (8.) The Library of the *Roman College* (Jesuits), said to contain 70,000 volumes;¹⁶ and, (9.) The *Vallicellana* Library (sometimes termed Library of the Oratory); chiefly noticeable for its manuscripts. They include many ancient classics of interest, and are singularly rich in materials for French history, especially in respect to

Foreign libraries. the relations which have subsisted between the Court of France and the Papal See.¹ Thus, if these statements be trustworthy, the nine chief libraries of Rome contain more than 41,000 volumes of MSS., and 700,000 of printed books.

Ambrosian Library at Milan. The Ambrosian Library at Milan owes its existence to the munificence of Cardinal Federigo Borromeo, nephew of Charles Borromeo, and his successor in the see of Milan, (1609). This prelate began to collect books, when a student at Rome; and enlarging his plan as he advanced in age and dignities, he, when raised to the archbishopric of Milan erected an edifice, placed in it his collection, and opened it to the public under the title of *Bibliotheca Ambrosiana*. Some of its choicest treasures carry back the visitor's imagination to the remote antiquity of the seventh century, when the monastery of Bobbio was founded by Scottish and Irish monks in the heart of the Apennines. When, in 1690, Montfaucon visited the *Ambrosiana*, it had accumulated 40,000 volumes, conveyed, he says, "from Thessaly, Chio, Corfu, the country of Otranto, and Calabria."² . . . Two or three years later our own Addison paid a similar visit, and his first reflection is,—“to show the Italian genius, they have spent more money on pictures than on books. . . . *Books are, indeed, the least part of the furniture that one ordinarily goes to see in an Italian library.*”³ So variously does the same object impress different beholders, and so true is it that the eye sees what it brings.

This library contained, in 1836, according to the statement of its librarian, Signor Amati, nearly 100,000 volumes of printed books, and 4633 volumes of MSS., comprising about 18,000 separate works or articles.⁴ No numerical return for the *Ambrosiana* appears in the Foreign Office Correspondence of 1850–52. It is, however, very probable that a similar (and unintentional) mistake was made in reckoning the number of volumes of printed works in this library, as that which is known to have been made in its neighbour, the *Brera*,⁵ and that the former does not really possess, even in 1857, much more than 80,000 printed volumes, and 5500 MSS.; and there is annexed to it a gallery of pictures, statues, antiques, and medals, comprising many articles of great rarity and value. In the department of MSS. is a solitary but enormous volume of the physico-mathematical works of Leonardo da Vinci, with his designs representing machines, with figures and notes, collected by Pompeo Leoni; it was presented by a citizen named Galeazzo Arconati, who generously refused a vast sum for the precious treasure, and, to secure the possession of it to his country, consigned it to the Ambrosian Library as to an inviolable sanctuary. The sanctuary, however, was violated by the French in 1791, who seized the cherished relic of Leonardo's genius, and sent it to Paris;⁶ but what an abuse of victory enabled them to carry off, the fortune of war at length compelled them to restore. The same department also includes the famous Virgil, with annotations by Petrarch, in his own handwriting, with his impassioned note, in eight lines, regarding Laura; ten letters of Lucretia Borgia, addressed to Cardinal Bembo; the Missal of Cardinal Borromeo, richly illuminated; and, amongst various early Greek manuscripts, a

Josephus, translated by Rufinus, on papyrus, written on both sides of each leaf. Manuscript books upon this material are of the greatest rarity, and this volume, according to Montfaucon, was 1200 years old, or of the fifth century. The MSS. in this library were chiefly collected from the suppressed monasteries; and, in particular, those which came from Bobbio are of peculiar value. Most of the Ambrosian palimpsests belonged to this collection, including fragments of Cicero's *Orations*, and the Letters of Marcus Aurelius and of Fronto. There is also a Psalter of the seventh century, with the *Commentary* of St Jerome, filled with Gaelic glosses in the ancient Irish character.⁷ Cardinal Angelo Mai, afterwards librarian of the Vatican, formerly held the same office in the Ambrosian Library at Milan, and there commenced those researches which have entitled this distinguished scholar to the lasting gratitude of the learned. The Brera Library at Milan was counted in 1845, and found to contain 104,298 volumes. In 1847 it contained 108,971 volumes;⁸ and in the preceding eleven years the average annual rate of increase was 2180 volumes; so that its present numbers will probably be about 125,000 volumes of printed books, and nearly 1000 volumes of MSS. The other libraries of chief note in the Lombardo-Venetian territory are those belonging to the Universities of Pavia and Padua. These libraries contained, at the end of 1846: the first, 70,564, the other 79,226 volumes; and are open ten months in the year, four hours in winter and six in summer, every day excepting Wednesdays, Sundays, and holidays.⁹

Bologna, celebrated for its scientific and literary institutions, and its academy for the encouragement and promotion of art, boasts likewise a great public library. This extensive collection is especially rich in the literature of the natural sciences; and in Oriental MSS. Of Arabic alone there are 550, including a superb Dioscorides, and a curious atlas. It consists of above 105,000 printed volumes, and about 6000 MSS.;¹⁰ is contained in the Manfredi Palace; and is open to the public six days in the week, during nearly eleven months in the year (*giorni festivi*, of course, excepted). Among the MSS. the most precious is a Lactantius, in square quarto, of the sixth century, written in uncial letters; the Four Gospels, in Armenian, with charming miniatures, of the twelfth century; a Greek MS. of modern date,—a sort of medical commonplace book,—which is believed to contain some unedited fragments of ancient authors;¹¹ and 200 volumes of manuscript collections of the celebrated naturalist Aldrovandus. Mezzofanti was long librarian here; and a visitor who profited by his polite readiness to exhibit the rarities of the collection, has noted that on one occasion he produced a Mexican MS. which had puzzled all the pundits of Bologna, even himself included. The other universities of the Roman states are also possessed of considerable collections of books. That of Perugia, founded as early as 1320, has a library of 30,000 volumes;¹² that of Ferrara, founded at a much later period (1646), has a library containing no less than 80,000 printed volumes, and 900 MSS.;¹³ and the three universities of Macerata, Urbino, and Camerino, have each libraries, though upon a smaller scale. The first named

library, otherwise *Mozziana*, contains 12,000 printed volumes, and 68 MSS. The second, interesting, as containing some poor relics of the once noble library of the Urbino *Dukes*, is beginning to be cared for, say recent travellers, with somewhat more of energy than hitherto. The last of them appears to be the smallest and least valuable of all the papal libraries. The most interesting books in the Library of Ferrara, are the autograph manuscripts of the *Orlando Furioso*, in some places so interlined with changes and alterations by the author, as to be scarcely legible; and of the *Gerusalemme Liberata*.¹ It also boasts of a remarkable series of the early editions of Ariosto, now of the greatest rarity. The Town Library of Ravenna contained, according to Valery, at the date of his last visit, more than 40,000 printed volumes, and 700 MSS. Amongst the former are comprised about 700 editions (according to the same authority), of the fifteenth century, some of them of the greatest curiosity.² The once celebrated papyri of Ravenna have nearly all disappeared.

Florentine
libraries.

The public libraries at Florence are the *Mediceo-Laurenziana*, or Laurentian; the collection bequeathed to the public by Magliabechi, by whose name it is distinguished; the *Marucelliana*; the *Riccardiana*, which was purchased, in 1815, of the Riccardi family; and the Library of the *Belle Arti*, containing the books which were taken out of the suppressed convents.

Mediceo-Laurentian
library.

The Mediceo-Laurentian Library, which is contained in the convent annexed to the church of San Lorenzo, was commenced by Cosmo de' Medici, the father of a line of princes whose name and age, as Roscoe has said, are almost synonymous with the restoration of learning. "His credit," says Gibbon, "was ennobled into fame; his riches were dedicated to the service of mankind: he corresponded at once with Cairo and London; and a cargo of Indian spices and Greek books were often imported by the same vessel."³ As the natural disposition of this princely merchant led him to take a very active part in collecting the remains of classical antiquity, so his wealth and extensive commercial intercourse enabled him to gratify his taste to the fullest extent. He enjoined his friends and correspondents, as well as the missionaries who travelled into remote countries, to search for and procure ancient manuscripts in every language and upon every subject. He availed himself of the services of the most learned men, his contemporaries; and the situation of the Eastern empire, then falling into ruins, afforded him an opportunity of obtaining many valuable works in Hebrew, Greek, Chaldaic, Arabic, and other languages.⁴ After the death of Cosmo, his son pursued the same object with steady perseverance, and added considerably to the treasures which had been accumulated by his father. But although the ancestors of Lorenzo de' Medici had laid the foundation of the Laurentian Library, the honour of raising the superstructure belongs to Lorenzo himself, whose assiduity and liberality in enlarging his collection of books, manuscripts, and antiquities, were unbounded. To this object his time and his fortune, exceeding that of princes, were equally devoted. Shortly after the death of Lorenzo, however, this matchless collection was dispersed by the Florentines themselves.

Foreign
libraries.

In the disturbances which attended the expulsion of Pietro, and the approach of the French under Charles VIII. (1494), miserable plunderers openly carried off, or secretly purloined, whatever they could lay their hands on that was rare, curious, or valuable. Part of the library, however, was preserved by the interposition of the magistrates, but only to encounter new perils. The Florentine treasury becoming exhausted, the rulers of the day (amongst other expedients) sold the books to the Dominicans of St Mark. At this point the history of the *Laurenziana* becomes linked with the fortunes of the still older library of that monastic community, a collection of which Cosmo may be said to have been the founder, conjointly with Niccolo Niccoli. The 800 volumes (or at least the survivors of them) which Niccoli had bequeathed to his fellow-citizens, and which Cosmo had redeemed from a lien that had well nigh annulled the legacy, and had committed to the custody of the Dominicans, were now united with what remained of the domestic library of Cosmo himself, and of the more splendid acquisitions of Lorenzo. But, within two years, the misdirected zeal of the impulsive Savonarola,—for a while virtual King of Florence,—scattered with lavish hand some of the choicest books as presents, and dragged others with contumely to a vast bonfire in the public square!⁵ In this wild *auto-da-fé*, Boccaccios, Petrarchs, and Pulcis, in all the pomp of their rich illuminations and sumptuous bindings, mingled their ashes; with this result, amongst others,—that the frenzied hatred of Dominican monks in the fifteenth century connects itself with the scarcely less frenzied love of English peers in the nineteenth, as cause with effect. Had no Savonarola burnt *Decamerons* in the Florence piazza in 1497, assuredly no Duke of Marlborough would have given L.2260 for a *Decameron* in 1812. After Savonarola's death, the Dominicans, falling into embarrassment in their turn, sold their library (1508) to Pope Leo X., who caused it to be removed to Rome. It was re-conveyed to Florence by his successor Clement VII., who, by a bull dated the 15th of December 1532, made provision for its future security.⁶ In 1571 the Grand Duke Cosmo I. made the library public. This library, the noblest monument which the Medicis have left of the glory of their line, contains 6952 MSS., of which a very large proportion—despite so many losses, and such strange vicissitudes—combine rarity and value. They have been described in a catalogue of thirteen folio volumes, compiled by the learned Bandini,⁷ formerly librarian, at the suggestion of the Emperor Francis I., who presented him with a sum of money towards the expenses, and made him promises of further assistance, which, however, were rendered unavailing by the death of that sovereign.⁸

The most celebrated manuscripts in the Laurentian Library are,—the Virgil of the fourth or fifth century, the long missing leaves of which Mai had the good fortune to discover in the Vatican; the famous *Pandects* of the seventh century, in two volumes, brought to Florence in 1406; a Tacitus, translated in the ninth century from one dated in the year 395; the *Decameron*, supposed to have been written in 1384 by Amaretto Mannelli; the *Epistolæ Familiares* of Cicero, copied by Petrarch; a Tasso, with copious notes, in the hand of Politian; and many Dante MSS.

¹ There are also a few Arabic MSS. *Archives, ut supra*, (1850), p. 395.

Foreign
libraries.

of the highest interest, although but copies (Dante's autographs have perished)—amongst them the celebrated letter discovered by Mehus, and published first by Dionisi, and afterwards by Foscolo.

Of printed volumes, the Laurentian Library possesses but 1316; having always been pre-eminently, and, until a recent date, exclusively, a library of MSS. The famous collection of first editions of Greek and Latin classics, formed by Count Angelo d'Elci, has worthily created an exception to the rule. It amounts to 1207 volumes; and besides these there are 109 other volumes, which have at various times been presented by, and accepted from, their respective authors.

Maglia-
bechi
library.

Magliabechi, from being a servant to a dealer in vegetables, raised himself to the honourable office of librarian to the Grand Duke of Tuscany at Florence, and became one of the most eminent literary characters of his time. The force of natural talent overcame all the disadvantages of the humble condition in which he had been born, and placed him in a position to make his name known and respected. But he endeavoured to deserve still better of his countrymen, by presenting them, some time before his death in 1714, with his large and valuable collection of books, together with what remained of his fortune, as a fund for its support. This constituted the foundation of the Magliabechian Library, which, by the subsequent donations of several benefactors, and the bounty of some of the grand dukes, was so much increased both in number and value, that it may now vie with some of the most considerable collections in Europe. The books printed in the fifteenth century have been described by the librarians, Fossi and Follini, who dedicated the catalogue¹ to Ferdinand III. Another and larger catalogue was completed in 1856, by the late learned and laborious bibliographer, Giuseppe Molini (who died in December of that year), to whom the *Magliabechiana* is also indebted for an improved rearrangement; but there is no printed catalogue of the library. It is particularly rich in the early productions of the Italian press, which are described by Follini alphabetically, with much accuracy of detail; and to these descriptions are added brief notices of the lives of the different authors. The Magliabechian Library is under the same roof with the Uffizi Gallery. It contains about 140,000 volumes of printed books,² and 10,000 manuscripts. Among its richest treasures are,—the Mentz Bible of 1462, on vellum; the first edition of Homer, printed at Florence, 1488, also on vellum, with miniatures, and presented to Pietro de' Medici; a copy, on vellum, of the Dante of 1481, embellished with miniatures within and nielle without, presented by Landino to the senate of Florence; a magnificent copy of the *Anthologia* of Lascaris, 1494, also a present to Pietro de' Medici; with other vellum copies of singular beauty of the Florentine history of Leonardo Aretino (Acciaiolì's translation, Ven. 1476); and of the *Argonautica* of Apollonius (Flor. 1496).³ These are volumes which would give importance to any library.

Marucel-
lian Li-
brary.

The Marucellian contains 33,435 volumes of printed books, and 1375 volumes of MSS.; the Riccardi collection

about 20,000 volumes of printed books, and 3600 MSS., many of them of the highest value. The collection of the *Belle Arti* contained, when the official returns of 1835 were made, 11,000 volumes.⁴ There is no mention of it in those of 1850. The disbursements on account of these various libraries are made by their respective librarians, under the control of the Minister of the Interior; the sums ordinarily expended, however, are but trifling.

The *Biblioteca Palatina*, or private library of the Grand Duke in the Pitti Palace, dates but from 1815; the old library of the Pitti having been distributed by Duke Leopold amongst the various public collections of the city; the Poggiati collection, and a part of that of Count Reviczky having been its groundwork. Literary researches meet with no obstruction, but as it is not public property, there is no account of its extent in the recent official returns. Valery states that, when he visited it, the number of printed volumes exceeded 80,000, and that of MSS. was nearly 1500. It is, unquestionably, a splendid collection, and in all probability keeps better pace with the progress of publication abroad than does any other library in Florence. Its strength, too, in Italian literature is proverbial. Amongst the *Cimelia* of the Palatine Library are the MSS. of Machiavelli, rich in correspondence and in state papers (although a portion of them has found its way to the British Museum); and those of Galileo, including a noble series of letters (now in course of publication), and of works published by his assistants, and annotated by himself. This collection—which includes the papers of Torricelli, of Viviani, and of other eminent philosophers—amounts to more than 300 volumes.⁵ The libraries of the University of Pisa and of the city of Sienna are valuable, the former possessing about 62,500 volumes,⁶ and the latter about 35,000 volumes of printed books, and 3417 MSS.,⁷ to which an annual addition of books to the value of 100 scudi is respectively made. In almost all the provincial towns of Tuscany, there are also to be found public libraries, more or less extensive, which are all placed under the control of the communal magistrates.⁸

There are four public libraries (or libraries so-called), at Naples, viz., the Royal Library, the Brancacciana Library, the Library of the University, and the Library of the Oratorian Priests of St Philip Neri. The Royal Library (*Biblioteca Borbonica*) contains about 200,000 printed volumes and 4000 MSS.; the University possesses 25,000 volumes; the convent of St Philip Neri has but 18,000 printed volumes, and 60 MSS.; the Brancacciana contains 70,000 volumes of printed books, and about 1000 volumes of MSS., relating chiefly to Neapolitan history.⁹ This library was founded by the bequest of Carlo Brancaccio in 1688. The public have free admission to read in these libraries, but no books are allowed to be taken away. They are all professedly open every day, for periods varying from six hours to two hours daily, excepting on holidays, when they are closed. But how easily liberality on paper may be turned into its opposite in practice will be seen by the testimony of an English visitor towards the close of 1856:—"Nominally open from twelve to two o'clock," he says,

¹ *Catalogus Cod. Sec. xv. impressorum Bibliothecæ Magliabechianæ*, Flor. 1793-95, fol.

² "I volumi stampati si possono giudicare circa 140,000, compresi i duplicati che per ordine superiore sono stati già verificati e separati (*Official Returns to Foreign Office*, 1850, p. 368)." According to Molini, these duplicates amount to 11,000; and many of them occur again and again in other Florentine libraries. This superfluity of books in one direction, combined as it is with paucity of books—foreign ones especially—in another, constitutes one of his arguments for combining the six libraries of the city into three main collections: (1.) *Medical*; (2.) *Legal*; (3.) *General*,—containing all the MSS., and all the printed books relating neither to medicine nor to law. With the bulk of the duplicates he proposes to enrich the provincial collections. (*Progetto di Riordinamento per le Pubbliche Librerie di Firenze*, Fir., 1848, 8vo, p. 3.) The plan has suggestive worth in it, beyond the limits of Tuscany. Some very partial effect has been already given to it, we believe, but the Tuscan returns of 1850 contain no allusion to the subject. The main libraries of Florence continue as yet to be distinct collections.

Foreign
libraries.

"the Borbonica is twice a-week closed at one, under pretence of cleansing, . . . and on fête days innumerable. . . . Having entered, the difficulty is to find the books, for there is scarcely any arrangement,—and why should there be when so many are prohibited? . . . Not only are Filangieri, Bentham, the *Bibliothèque Universelle de Genève*, for instance, refused, but the *Kosmos*. At all events, an express permission must be obtained from Rome to read it."¹ Valery has mentioned a peculiarity in the arrangements here which is probably unique: "One room is set apart for the blind, who pay persons to read to them. . . . The picturesque image of Dante must be often realized there, 'Lo mento a guisa d'orbo in su levava.'"² The expenses of the Royal Library are included in the same grant with those of the Brancacciana. It is entitled to two copies of all books printed in the kingdom of Naples; and 4000 ducats (L.687) are annually appropriated to the purchase and binding of books.³ The expenses of the Library of St Philip Neri, or of the "Girolomini," are defrayed out of the funds of the convent to which it belongs. The Brancacciana and University Libraries are, each of them, entitled to one copy of every book printed in the city of Naples. This collection is rich in ancient books. Its special show volume is a finely illuminated copy of the *Tragedies* of Seneca. The Royal Library was originally formed of the old Farnesian Library, brought from Rome to Naples by Charles III.; and of those of the Jesuits, and various suppressed convents. The collection of early printed books is considerable, and has been described in a catalogue by the Chevalier De Licteris, Naples, 1828–41, 4 vols. folio.⁴ Here is a copy of the *Catholicicon* of 1460, and the Bible of 1472, both upon vellum; the Petrarch of 1470; the Dante of Mantua; the first edition of the celebrated mediæval legist, Bartholus, of Sasso Ferrato, 1471, the first book printed at Naples, and other specimens of the early Neapolitan press. But the most choice book is one of the three or four copies, printed on vellum, of the first edition of Homer, 1488. The volume of the *Iliad* is, unfortunately, defective. Several leaves, on account, no doubt, of their illuminations, having been ruthlessly torn out of the volume.

The *Odyssey* has fortunately escaped, the first page being illuminated in the best style of Italian art, with the arms of the proprietor; and there is also inserted one of the most charming portraits in existence, the full size of the book, of one of the Farnese family, if not by the hand of Raffaele, at least by his master, Pietro Perugino. Among the MSS., besides the celebrated *Hours* of Giulio Clovio, there are many of great beauty and interest; virtually, however, they are sealed books. Even eminent scholars, bearing the commission of the French Ministry of Public Instruction, have wasted a fortnight in waiting for facilities which were, after all, refused. "The palace of the Studj bears for its device, *Jacent nisi pateant*; and for years all the MSS., and part of the *Museum*, were locked up." Such is the testimony of M.M. D'Aremberg and Renan, in their report to the minister of 25th July 1850.⁵ There are no public libraries in any of the provincial towns of the mainland, excepting Brindisi,⁶ which has a small collection bequeathed by Monsignor de Leo; but in every diocese there is a library belonging to the See, to which, upon application, admission may at all times, it is said, be readily obtained.⁷ In Sicily—compared with which Naples has always been a

Foreign
Libraries.

laggard—the provision of public libraries is somewhat more ample, and their management more enlightened. The Palermo collection, called indifferently the University,⁸ or the "Communal" Library, contains nearly 80,000 volumes of printed books. The Jesuits of Palermo have another library, reported to contain about 40,000 volumes. The Library of Messina is stated to contain about 20,000, and that of Catania, nearly 40,000 volumes of printed books. Collectively, these four libraries contain upwards of 1200 MSS. There are also libraries of less importance at Girgenti, Syracuse, Termini, Nicosia, Caltagirone, and Trapani.⁹ The monastery of Monte Cassino retains its library (of about 18,000 volumes, according to Valery), but with diminished lustre. The collection, however, still includes some fine specimens of early typography. Amongst the MSS., amounting to about 800 volumes, the most ancient is a Latin version of Origen's *Commentary on the Epistle to the Romans*, dated in the year 569; a Virgil of the fourteenth century, copied from one of the tenth, in the Lombard character; a Dante of the thirteenth century; the Offices of the Virgin, with charming miniatures, executed in 1469 by Bartolomeo Fabio di Sandalio; and an extensive series of original letters of Mabillon, Montfaucon, Muratori, and other learned men of the last century, from which M. Valery has published an interesting selection.¹⁰ In the archives of the monastery there is preserved a very remarkable series of more than 40,000 deeds and records of various kinds,¹¹ including many original charters, papal bulls, and other like documents, from the eighth century. It is rich in materials for the history of Apulia, Calabria, and Naples. The archives occupy three apartments; and, if it be borne in mind where they have been preserved, and what they have survived, may well be termed a wonderful collection.

The Italian libraries which yet remain to be mentioned are numerous, and some of them considerable, particularly those of Venice and Turin. The Library of St Mark at Venice forms the west side of the Piazzeta, or Palazzo Reale. This library was commenced in the fourteenth century, the original collection having been begun by Petrarch, who gave some books to the Republic in 1362. About a century later, Cardinal Bessarion presented to the Republic the curious collection of MSS. which he had formed in Constantinople, in Egypt, and in Greece; and further additions were subsequently made to it by other cardinals. But, strange as it may seem, especially when we read in Bessarion's letter to the Doge, which accompanied the gift (30th April, 1468), the words "*venerable* Library of St Mark," there is not a scintilla of evidence to show either (1.) that the writer had in his memory the gift which Petrarch had so ardently wished should prove the groundwork of a Venetian library; or, (2.) that the new donation put it into any one's mind to ascertain the fate of the old one. Bessarion's collection became the true foundation of the present *Marciana*; and it appears that the books of Petrarch remained entombed until 1635, when researches into his biography gave Tommasino a clue which ultimately set the then procurators of St Mark to ransack a neglected and dust-choked little room, in near proximity to the famous bronze horses. Here the MSS. were found, some petrified into fossils, and others ready to crumble in the hands of the discoverers. The Library of

Foreign
Libraries

St Mark is now deposited in two apartments, one of which is appropriated to MSS., whilst the other contains the printed books. The number of volumes of printed books was officially stated at 65,000 in 1822;¹ at 85,602 in 1835;² and at 103,859 in 1848.³ That of MSS. at about 5000, in 1822; and, by Mr Curzon, as amounting in 1840 to nearly 10,000, more than 1000 of which are upon vellum.⁴ Amongst these MSS., it need scarcely be said, but a very small number of the Petrarch donation is preserved. They include a Homer, translated by Leontio Pilato, and copied in the handwriting of Boccaccio; several important Greek MSS.; an Evangelarium, according to Morelli, 1000 years old; the *Laws of Lombardy*, the most valuable copy known; and the original manuscript of Father Paolo Sarpi's *History of the Council of Trent*, corrected with his own hand. Of printed books, several of great value, on vellum, were carried by the Austrians to Vienna; but there still remain some choice specimens of the Aldine press; and a copy on vellum of the first edition of Homer, unrivalled for beauty of condition. It was among the spoils restored by the French in 1815, and Van Praet has expressed his deep regret at seeing the Royal Library at Paris deprived of this and other similar works.⁵ Though small when compared with many other libraries of the Continent, this collection includes an unusual proportion of rare and valuable books.⁶ In the Armenian convent, in the island of San Lazaro, close to Venice, there is a small but interesting collection of books and of Oriental MSS. One of these, the Gospels of Matthew and Mark, is a square quarto of the eighth century; another is a complete Armenian Bible of the twelfth century. The library attached to the University of Turin contained, in 1846, according to the University historian, 110,000 volumes;⁷ and, in September 1849, according to an official return, nearly 121,000 volumes of printed books, and a rich collection of MSS., amounting to nearly 3000.⁸ It is open to the public in general every day except festivals, during ten months of the year. Attached to the University of Genoa, is a library, consisting, in 1849, of about 39,200 printed volumes, and 800 MSS. Genoa has three other public libraries, containing in the aggregate about 60,000 volumes.⁹ The University Library of Padua contained, in 1847, upwards of 78,000 volumes of printed books, and 1672 MSS.¹⁰ Some other libraries in that city contain MSS. of interest, as do also the Chapter Libraries of Verona, Novara, and Vercelli. From a rescribed manuscript discovered by Niebuhr, the Roman historian, in the collection of the Chapter of Verona, was deciphered and published no inconsiderable portion of the *Institutions* of Gaius, which served as a model to Justinian, or rather to

Tribonian, in framing that elementary exposition of principles which is prefixed to the *Digest*. The writing is in uncial letters, perhaps of the fourth century, and the superscribed MS. itself—containing the *Homilies* of Jerome—can scarcely be older than the seventh. The same collection contains a palimpsest Virgil of the third or fourth century, overwritten with the Gregorian *Comment on Job*, in a Longobardic hand of the eighth. Mr Curzon looks on this as anterior to the Medicean Virgil.¹¹ The Library at Mantua contains upwards of 40,000 volumes of printed books, and about 400 MSS.¹² Some of its books are curious, and it is very freely accessible.

Foreign
Libraries

IV. GERMANY

The libraries of Germany, taking that name in its widest Libraries acceptance, are, some of them, of the first order, and many of them extensive and important; but we confine our many notices exclusively to the principal collections, which we shall describe mainly in the order, not of place or of time, but of their relative magnitude and value.

The Imperial Library at Vienna was long esteemed inferior only to that of the Vatican and to the Royal Library at Paris for the rarity and value of its contents. It was founded, as early as the year 1440, by the Emperor Frederick III., who spared no expense to enrich it with printed books, as well as manuscripts in every language. By the munificence of succeeding emperors, numerous important and valuable accessions were made to the library, amongst which may be mentioned the famous collection of John Joseph Fugger; the collections of Tycho Brahe, of Busbequius, of Cuspinian, and of Hohendorff; the large and interesting Library of Prince Eugene, and a considerable portion of the Library of Corvinus. In 1575 it was declared publicly accessible for the promotion of learning. The Imperial Library occupies eight spacious apartments, and a ninth is appropriated to a very valuable collection of medals and other curiosities.¹³ The Grand Library is a large central room, the floor of red and white marble, diamond-wise. The vaulted oval dome, 193 feet in height by 57 wide, supported by columns of scagliola, with its painted ceilings, and marble statues, exceeds in splendour any similar room in Europe. In Dibdin's *Bibliographical Tour* there is an admirable representation of it. The books in this great room, being for the most part from the fine library of Prince Eugene, are in rich old morocco bindings, with arms on the sides. The entire collection, according to the latest authority, now consists of more than 365,000 volumes of printed books, and about 20,000 volumes of MSS.¹⁴ The books are disposed according to their sizes, and include

³ *Foreign Office Returns*, 1850, p. 110.

⁴ Curzon, *ubi supra*.

⁵ The privation, however, was far from being complete. A bystander who (in 1815) made some notes of what passed under his eyes, had opportunities of witnessing the active "requisitions" of the commissaries of the allied powers, for those literary trophies which had long been as keenly regretted by the losers, as they were proudly treasured up by the captors. The Prussians pre-eminently distinguished themselves for the fierce assiduity of their quest. But marvellous was the ingenuity which occasionally perplexed the poor commissioners who, catalogue in hand, had to scrutinize, first the books produced, and then the lists of those that had been carried off. Many travellers who visited the Royal Library, under favourable auspices, while the memory of these things was yet fresh, will recall the subdued but irrepressible glee with which choice books were sometimes shown,—books that had formerly been shown by other librarians to other visitors.

⁶ Balbi, in the appendix to his *Essai Statistique*, gives some very extraordinary particulars of the *Archivio Generale* at Venice, to which great attention is paid by the Austrian government. This unparalleled collection contains, he says, 8,664,709 stitched quires, divided into 1890 departments, and arranged in 298 apartments. But whether its value corresponds with its magnitude, is a point on which we are very much left to our own conjectures; nor would it be easy to determine to what extent Vienna may have been enriched at the expense of Venice. See *postea*, p. 419.

Foreign
Libraries

almost a complete series of *Incunabula*, exhibiting the origin and progress of the typographic art. The number of works printed in the fifteenth century is estimated at 15,000, of which perhaps 3000 are duplicates. Amongst these, the first place for rarity and value belongs to those printed upon vellum, including the *Psalter* of 1457; the *Rationale* of Durandus, 1459; the *Constitutiones* of Pope Clement V., 1460; the Latin Bible of 1462; *S. Hieronymi Epistolæ*, 1468; Cæsar, Apuleius, and Aulus Gellius, each of them in 1469; the Pliny of the same year, and also that of 1472, and many others, all in the finest condition. The Apuleius and the Aulus Gellius were once the property of Cardinal Bessarion, and are comparatively but recent acquisitions of the imperial collection. The Florence Dante of 1481, with the commentary of Landino, and the plates of Baldini, from designs by Botticelli, is likewise in this library. This is the finest copy extant, excepting that in Lord Spencer's collection, and each of them possesses twenty copperplates.¹ The Cimelia, or most remarkable rarities, are twenty-four in number. Amongst them are a tablet of bronze, containing the original *Senatus-consultum*, or decree of the Roman senate for the suppression of the Bacchanalians, passed in the year 186 B.C.;² the imperfect *Tabula Peutingeriana*, a travelling map of the ancient world, compiled in the eighth century, on parchment;³ and several palimpsests procured from the monastery of Bobbio. About 3000 of the MSS. are on vellum. Some deserve to be mentioned, on account of their singular rarity; as, for example, (1.) A Mexican manuscript,—a specimen of that curious coloured figure-writing which Lord Kingsborough's great work has made familiar to students. It is, as travellers are usually told, on human skin, or, much more probably, on deer-skin; (2.) The unique manuscript of the Fifth Decade of Livy, assigned to the sixth century, and reported to have been brought from Scotland by St Suelbertus, the apostle of the Frisians; (3.) A *Psalter* (*Codex Aureus*), being written in letters of gold, which belonged to Charlemagne; (4.) A manuscript of St Mark's and St Luke's Gospels, written in gold and silver characters; (5.) A manuscript of Dioscorides, with coloured drawings of plants, the characters marked with minute accuracy, written in the year 505, by order of the Princess Julia Anicia, only daughter of the Emperor Olybrius. This precious manuscript was brought from Constantinople in 1550 by the

Foreign
Libraries

celebrated Busbequius,⁴ ambassador from Charles V. to the Porte, by whom about 300 other Greek manuscripts were collected in the Turkish capital, including a manuscript of Pliny's *Historia Naturalis*, of contemporary date; and, (6.) An autograph manuscript of the *Gerusalemme Liberata* of Tasso. Besides these, there are in this collection fragments of Genesis, in uncial Greek of the fourth century, the letters of gold and silver, on purple vellum, richly ornamented with miniature paintings; a fragment on papyrus, containing the decrees of the third council of Constantinople, held in the year 680; the *Codex clathratus*, or fragments of the most ancient German translation of the Gospel of St Matthew, written in the early part of the eighth century;⁵ a German Bible, in six volumes folio, richly illuminated, written for the Emperor Wenceslas, who died in 1419; a French manuscript of the fourteenth century, written in large letters, according to the ancient orthography, profusely illuminated, and containing the history of Tristan, the celebrated Knight of the Round Table; together with many other rare, curious, and interesting works. The Greek MSS. in the Imperial Library have been described by Lambeck,⁶ Kollar,⁷ and Nessel,⁸ whose labours were confined to this class; and in the important and accurate work of Denis⁹ may be found an ample account of many of the Latin, with a few notices of Oriental MSS., the ages of the different MSS. being stated where these could be ascertained. Besides the cabinet of medals, there is also attached to the library a superb collection of engravings, reckoned to consist of 300,000, arranged and bound in 590 large folio volumes, 726 volumes of various sizes, and 322 portfolios. The collection of music contains 6000 works, theoretical and practical, in about 9000 volumes; and that of autographs amounts to nearly 10,000 pieces, classed under the heads of monarchs and princes, ministers and statesmen, poets, philosophers and men of learning or science, generals and renowned warriors, artists, and others.¹⁰ The sum allowed for the purchase of new books, independently of extraordinary grants, is about L.1100 annually.¹¹ The Imperial Library is open to the public every day, except on Sundays, holidays, and the vacations.¹² Here, however,—as in most of the greater Continental libraries—it is very reasonably expected that those who frequent it shall be students, not idlers, or seekers for mere amusement, and to

¹ Dibdin's *Bibliographical Tour*, vol. iii., pp. 291, 486, 518. See also his *Library Companion*, pp. 22, 581, 752.

² This is the same decree which is cited by Livy (lib. xxxix., c. 18); it was found in Calabria, on the estate of Prince Cigala. (*Voyage de deux Français*, tom. v., p. 136.)

³ For a long time this Itinerary was believed to be of the fourth century, and was identified with that Theodosian map alluded to in the well-known epigram of Sedulius,—*Hoc opus egregium, quo mundi summa tenetur*, &c.,—but the opinion is altogether untenable; although it is highly probable that its author (whomsoever he may have been) compiled it from ancient authorities, some of them perhaps older than the Itinerary of Antoninus. The Peutinger map has otherwise a curious history. Conrad Celtes discovered it at Spire, whilst searching for books and MSS. on behalf of the Emperor Maximilian I., to be placed in the Imperial Library. He seems to have looked on this remarkable document as out of the limits of his commission, and to have parted with it, either by gift or by sale, to Peutinger, who proposed to publish it, but died too soon. It then disappeared. Velsler, having vainly sought for it, published Peutinger's unfinished transcript. Seven years afterwards (1598), it was found in an old chest. Morelius then edited it, and it was subsequently republished by Berlius (1618), by Arnold (1682), and by Horn (1686). Then it disappeared again, and was not recovered until 1714. At length, after the lapse of 200 years, it found a secure place in that Imperial Library to which it should have gone at first; and thence, in 1753, it was superbly edited by Christ. von Scheyb. To complete these "Adventures of a MS.," it may be added, that a fragment of the missing portion of this most curious work has been recently discovered in the binding of a volume in the Public Library of Treves.

⁴ Of this manuscript Dioscorides, Busbequius himself has given a very interesting account. See Busbequii *Epistolæ*, lib. iv., p. 391.

⁵ These fragments were found in some old bindings of books.

⁶ *P. Lambeckii Commentariorum de Bibliotheca Cæsarea Vindobonensi libri viii.* (1665–79, fol.) The eight books occupy eight volumes. A fragment of the ninth volume is in Schelhorn's *Amanitates* (tom x., pp. 97–115). It would have taken seventeen more to have worked out the vast plan of the author. The rarity of the original edition is said to be owing to the avarice of Strellmayer, Lambeck's heir, who, under annoyance at the slowness of the sale, made a bargain with the War Department at Vienna, when paper was somewhat scarce, for the conversion of the remaining stock into cartridges. (Struvii, *Bibliotheca Historica Litteraria*, p. 594.) Kollar published a new edition in the years 1766–82.

Foreign Libraries this end dictionaries and school-books of all kinds, together with works of "light literature," are given out only on some literary purpose being assigned for their demand. For MSS. there is a special reading-room. Books are lent to the dignitaries and high functionaries of the empire, and to those scholars and literary men whose known position and responsibility ensure their safe return.

University and other Libraries at Vienna. In Vienna, the University Library ranks next to the Imperial Library. It contained in 1848, according to an official report, 120,609 volumes,¹ independently of the special collection attached to the observatory which occupied the same edifice. The present University Library dates but from 1777; the former collection—founded in 1435—having been long since incorporated with the Imperial Library. The University received the collections which had belonged to the convents suppressed by Joseph II.; and since 1806 it has had a right to a copy of every work printed in Lower Austria. Amongst what are called the private libraries, the most important is that of the Military Archives, established in 1801, upon a plan devised by the Archduke Charles. It contains 22,500 volumes,² chiefly on military science and geography; 20 large folio volumes of bulletins, gazettes, and journals, with an index; 73 atlases, with more than 3000 charts, maps, and plans of various kinds; and a small but curious collection of manuscript military memoirs, amongst which are those of Montecuculi, who commanded the imperialists opposed to Turenne, and of Prince Eugene. The Libraries of the Imperial Academy of Oriental Literature, of the Museum of Natural History, of the Philharmonic Society, and of the Imperial Archives, are also of great value. In the last are preserved some documents taken from the archives of Venice,³ and Marino Sanuto's original History of that republic, in 56 volumes, which was unknown when M. Daru published his celebrated work. The total number of libraries, public and private, in Vienna, is said to be fifty-three;⁴ and most, even of the latter, are accessible to students furnished with proper introductions.

Royal Library at Munich, &c The Royal Library at Munich, founded about 1660, by Albert V., Duke of Bavaria, is the most extensive collection in Germany, containing probably between 400,000 and 500,000⁵ volumes of printed books,—exclusive of a large number of duplicates, which were recently on sale,⁶—and 22,000 volumes of MSS.⁷ From a discourse on the origin and increase of the Library at Munich, delivered in 1784, by the Canon Steigenberger, then librarian (and translated into Latin by Vitali), it appears that the Hebrew, Arabic, Syriac, Greek, and Latin MSS. contained in this library even then formed a precious treasure; and, since that period, vast additions have been made to all de-

partments of the collection. The Royal Library, which formerly occupied a college which had belonged to the Jesuits, is now removed to a magnificent new building, in the style of a mediæval Italian palace. Among its MSS. we may specify a Greek New Testament, in uncial letters, of the eighth century; a copy of the Latin Gospels, of the same age; a New Testament, written in gold and silver letters, on purple vellum, of the ninth century; an Evangelarium and Missal, given by the Emperor Henry II. to the cathedral of Bamberg about the year 1020, most richly decorated with miniatures of the Byzantine school, the binding ornamented with carved ivory; a magnificent copy of the Seven Penitential Psalms, set to music for the chapel of the founder, by Orlando di Lasso, and richly illuminated. Its Oriental, and especially its Hebrew MSS., are both numerous and choice. The ancient MSS. relative to the art of music amount to a great number, and are exceedingly curious.⁸ A catalogue of the Greek MSS. in this library, compiled by Ignatius Hardt, was printed at Munich in 1804.⁹ Of printed books of the fifteenth century, the library is stated to possess (besides 50 block-books,¹⁰ some of them from the Haarlem press), 3500 without date, and 6000 with dates prior to the year 1500. Munich has also its University Library,—formerly at Ingolstadt, and removed to Munich in 1826,—which contained, in 1853, about 220,000 volumes of printed books, and 2000 MSS.¹¹

Royal Library at Dresden. The King of Saxony's Public Library at Dresden was founded in 1555, and now contains 305,000 volumes of printed books, besides 182,000 dissertations, and 2800 volumes of MSS.¹² The valuable library that formerly belonged to Count Bunau forms part of this noble collection, which is most complete in history generally, and in Greek and Latin classic authors. Amongst the printed books are some of the rarest specimens of early typography, including 600 of the Aldine editions, and many on vellum; besides a copy of the first edition of the *Orlando Furioso*, printed by Mazocco, "coll' assistenza dell' autore," in 1516, and other rarities. In the department of MSS. are,—another Mexican manuscript, said to be written on human skin, and containing, according to Thévenot, a calendar, with some fragments of the History of the Incas; *Liber de re militari*, on vellum, with superb paintings, in fine preservation, presented to an elector of Saxony by Matthias Corvinus; the original manuscript of the *Reveries* of Marshal Saxe, bearing at the end that he had composed this work in thirteen nights during a fever, and completed it in December 1733. Here also is a manuscript of Wycliffe's Testament, of the early part of the fifteenth century, let-

¹ *Foreign Office Returns* of 1850, p. 110.

² Petzholdt, *Handbuch*, ut supra, p. 371.

³ There seems to be ample warrant for this statement, notwithstanding the assertion, elsewhere repeated, that these Venetian archives have been "secured in perpetuity to the Municipality of Venice" (*Quarterly Review*, March 1855, vol. xcvi., p. 356). The very valuable article here referred to contains particulars of much interest respecting the present, or recent, state of these archives.

⁴ According to the enumeration of the learned and laborious author of the *Handbuch Deutscher Bibliotheken* (1853). Balbi, in his day, enumerated thirty-two Viennese libraries, without reckoning those of small importance. (*Essai Statistique sur les Bibliothèques de Vienne*, pp. 110, 111.)

⁵ The latest official return reads thus:—"800,000 volumes, including (*darunter*) 100,000 Dissertations and Pamphlets, 20,000 MSS. Yearly increase of books, 3000 volumes." Common as is extreme diversity of statement with respect to the extent of great libraries, there is no instance quite so extreme as this of Munich. The number of volumes has within a very few years been stated, in works of authority, sometimes as a little exceeding 400,000; sometimes as nearly 800,000. The main cause lies neither in the bad faith nor in the carelessness of writers, but in the childish vanity which prompts official persons, not merely in conversation, but when drawing up official reports, to shroud themselves in expressions of studied vagueness and obscurity, so that they may appear to be imparting information which, in truth, they are casting about to withhold. At least as much pains seems to be taken at Munich to mislead inquirers, as is commonly taken in Austrian libraries (for example), to give particulars which shall be minutely accurate. It has thus come to pass that the least trustworthy statements about the Royal Library of Munich are precisely the official statements. Yet, in most respects, the collection is so noble, that it need not shun comparisons strictly truthful and exact.

Foreign
Libraries

tered "Engl. Test. of a Lollar," and having the "Lessons and Pistles after the use of Salisburi;" a fine copy of the *Koran*, taken from a Turk by a Saxon officer at the last siege of Vienna, and said to have formerly belonged to Bajazet II.; a Greek manuscript of the Epistles of St Paul, of the eleventh century; and a very fine collection of portraits of the most celebrated persons of the seventeenth century, by Rabel, a French artist, the outlines only having been engraved.¹ Ebert's bibliographical MSS. were acquired after his death, and form a special collection, called *Eberti Apparatus Literarius*. There is a manuscript alphabetical catalogue, in 53 volumes folio; and a classed catalogue in about 120 volumes. The library occupies twenty-six light and elegant apartments in the Japanese palace, and the books are separated into classes. The expenses of the Royal Library are defrayed by the State. The sum of 3000 dollars, equal to L.450, is allowed yearly for the purchase of books, &c.² There are several other public libraries in Saxony, of which the most important are the University and Town Libraries of Leipsic. The first-named collection (which dates from 1543) contains more than 120,000 printed volumes, and 2500 volumes of MSS. The printed *Incunabula* exceed 2000 volumes.³ The Town Library was founded by Hulderich Gross, in 1677, and although, up to 1838, it had received no accessions of striking magnitude, it had come to be a very useful collection of about 40,000 printed and 1500 MS. volumes.⁴ In 1838 it received a noble gift, in the bequest by C. H. L. Poelitz, of an excellent political library of 25,000 volumes, with a fund for its future maintenance. This collection is kept distinct from the other portions of the Library. In the aggregate, the Town Library now numbers at least 90,000 printed volumes, and 2000 MSS.⁵ These libraries are freely open to the public, except on Sundays and holidays.⁶

Library of
Göttingen.

The library attached to the University of Göttingen contains about 360,000 printed volumes, and 3000 volumes of manuscripts.⁷ But its extent is its least recommendation; for it is not only the most complete amongst the university libraries, but there are very few collections of any kind in Germany which rival it in real utility. This library is mainly indebted for the pre-eminence it has obtained to the labours and exertions of the illustrious Heyne. In the year in which he came to Göttingen as second librarian, the entire control of the library was committed to him, and he became chief. From this moment commenced at once its extension and its improvement. When Heyne went thither, the library already contained from 50,000 to 60,000 volumes, which, compared with those of most universities, was a considerable collection. At his decease it had, according to the most moderate computation, increased, exclusively of extraordinary acquisitions, to upwards of 200,000 volumes.⁸ The system of catalogues which he established is elaborate but clear. There are, in fact, four catalogues connected with each other, and all of them are MSS. Every addition to the library is first entered in the *Manual* of the year, in which are concisely written the title and date of the book, and the day of its reception. Then the book is entered with its full title in the *Accession Catalogue*, which is also commenced with every year, and forms at its close four volumes; the first containing entries of books on theology;

the second, of books on jurisprudence; the third, of those on history; and the fourth, books in the other classes. These two catalogues are intended more particularly for the use of the librarians; the remaining two are for readers. The third of the series is a complete *Alphabetical Catalogue*, in which every book is entered under the author's name, when given, or, when not given but known, with a reference thereto under the chief word of the title. Every book of which the author's name is not known, is entered under such chief word of title; and, on one side, are also entered the date and form, with reference to the entries of the same book in the *Manual* and the *Accession Catalogue*; on the other is entered that heading in the classed catalogue to which the book belongs. Lastly, the book is entered in the *Classed* or *Scientific Catalogue*, according to its subject, and is then placed in its appropriate division of the library. Thus, the *Alphabetical Catalogue* answers the question, whether or not the known book of a known author, or the anonymous book of which the title is accurately remembered, is in the library, and, if there, where it is to be found; and the *Scientific* or *Classed Catalogue* shows what books are contained in the library upon any given subject. Such is a brief account of the mechanism of this very useful library.

Foreign
LibrariesRoyal li-
brary at
Berlin.

The Royal Library at Berlin contains nearly 500,000 volumes of printed books, and about 10,000 volumes of MSS. This collection includes works upon almost all the sciences, and in nearly all languages, but it is perhaps most complete in the sciences. Amongst the MSS. are several Egyptian deeds, written on papyrus, in the demotic or enchorial character, but whether with or without Greek registries, we have not ascertained. Professor Kosegarten, in his *Commentary on the Ancient Literature of the Egyptians*,⁹ has published facsimiles of a considerable portion of one of these, and of the *exordia* of twelve others, with interlinear translations in Latin, according to Dr Young's method of interpretation. Its Oriental section is very rich, and comprises the entire series of Sanscrit MSS. which had been formed by Sir R. Chambers, chief-justice of Bengal. The MS. department also includes several MSS. of Veyssière de Lacroze, the celebrated author of the *Lexicon Egyptiaco-Latinum*, once librarian here, and, amongst them, his reply to Bergier, in which he mentions the additions made to the Royal Library, the librarians, the number of books at the time when he wrote, and the curious articles contained in the collection. The *Alphabetical Catalogue* of this most extensive library is very complete; and six persons have been regularly employed in preparing a revised, or rather a new, classed catalogue. The former extended, in 1851, to upwards of 650 MS. volumes; the latter exceeded 250.¹⁰ Two volumes of a new printed catalogue of the MSS. have been published. The sum ordinarily allotted to acquisitions is about L.1800 a-year; but this amount is sometimes considerably increased by special grants,—as, for example, on occasion of the purchase of the Meusebach collection,—and at other times, when the latter have been of unusual cost, somewhat diminished.¹¹ There is perhaps no library in Germany which is now more efficiently conducted. Among early printed books there are several block-books;—the *Rationale* of Durandus, 1462, on vellum; the Aldine Petrarch, 1501; also,

¹ *Voyage au Nord de l'Europe*, vol. i., p. 71, et seqq.² Petzholdt, *Handbuch*, ut supra, p. 234.³ Appendix to Report on the British Museum, p. 495.⁴ *Foreign Office Returns* of 1850, p. 262. The official statement runs thus:—"In the University Library, there are nearly (ungefähr) 350,000 volumes of printed books, counting each individual volume, whether it be a [bound] pamphlet of a few leaves, or a volume containing 50 or more Tracts or Dissertations bound together." This is precisely the mode of enumeration which has been adopted at the British Museum (Panizzi, *Evidence before Brit. Mus. Commission*, 1849, p. 261); and if it were uniformly followed, would afford a firm and ample foundation for the comparative statistics of libraries.⁵ *Foreign Office Returns*, ut supra, p. 304; Comp. Petzholdt, *Handbuch* (1853), p. 36.⁶ *De Prisca Egyptiorum Literatura Commentatio I.* (Vimaribus, 1828, 4to.)⁷ Pertz, *Die Königliche Bibliothek in Berlin in den Jahren 1851-53* (Berlin 1854, 8vo), p. 1.⁸ *Foreign Office Returns*, 1850, p. 345.⁹ *Ibid.*, p. 229.¹⁰ *Ibid.*, p. 230.¹¹ Pertz, in *Serapeum* (1852), vol. xiii., p. 20.

Foreign Libraries on vellum, Luther's Bible. The collection of historical portraits amounted in 1851 to nearly 30,000.¹

Library of Stuttgart The Public Library at Stuttgart contains about 245,000 printed volumes, and 3230 MSS.² The collection was formed—first at Ludwigsburg in 1765, and removed to Stuttgart ten years afterwards—by the purchase of private libraries, the union of some State libraries, and those of suppressed monasteries. It is divided into three departments, each of which is under the superintendence of one of the librarians, who are charged with the purchase and binding of books, the keeping of catalogues, and other duties. The general government of the library is vested in directors, who endeavour, as far as their means allow, to procure everything that is of real worth. All booksellers in the kingdom are required to furnish a copy of every work published by them. To certain persons, and under certain regulations, books are allowed to be lent out from the library. The ordinary annual expense of the establishment amounts to about 9000 florins (L.750), of which about 6000 (L.500) are expended in the purchase of books; and it is defrayed out of the public treasury. The collection of Bibles is said to be the largest in the world, amounting to 8544 volumes, in sixty different languages. Such anxiety is felt to make this Biblical series as complete as possible that, a few years ago, a set of the *Acta Sanctorum* of the Benedictines was given in exchange for a copy of the famous *Psalter* of 1457. The University Library at Tübingen contains about 200,000 printed volumes; 50,000 dissertations, and 2000 MSS.³

Other German Libraries. The present Ducal Library of Wolfenbüttel dates from 1604, and is little inferior to that of Stuttgart; it contains at least 190,000 printed volumes, with more than 4000 manuscripts.⁴ Its choice treasures, both of MSS. and of early printed books, are numerous, and have been well described by Dr Schönmann.⁵ Here, too, the collection of Bibles is large and precious. Besides the libraries connected with various public institutions, such as the Senkenberg Museum, and the Staendel institution for the fine arts, there is a public library at Frankfurt, called the Town Library, in a handsome modern building facing the river. In the vestibule are various Roman antiquities found in the neighbourhood. This collection contains nearly 80,000 volumes of printed books, and 1000 volumes of MSS.,⁶ of which 20 are Abyssinian, 12 Turkish and Persian, 6 Hebrew, 2 Indian and Burmese, and the rest in Latin, German, and other languages. No catalogue of this library has been published since 1728; but there are good MS. catalogues. The annual expense, which amounts to about 5200 florins (L.434), is contributed by the public treasury.⁷ The Library of Naumburg was founded in the sixteenth century by Julius Pflug, bishop of that place, who is celebrated in ecclesiastical history as a zealous opponent of the Reformation, and as one of the three divines deputed by Charles V. to draw up the plan of the *Interim* in 1548. In the seventeenth century this library received a further augmentation by the purchase of the collection of books formed by Thomas Reinesius. The printed books and MSS., though few in number, are of considerable value. Amongst the latter are—the *Scholia* of Olympiodorus

on several of Plato's *Dialogues*, written in the sixteenth century; a fragment of Orpheus's *Argonautics*, of the fifteenth; the *Olympic Odes* of Pindar, of the sixteenth, apparently transcribed from an ancient manuscript, and including critical notes by Richard Croke; the *Cassandra* of Lycophron, with the *Commentary* of Tzetzes, dated 1438; and several tracts of Jamblichus on the Pythagorean philosophy, belonging to the fifteenth century.⁸ At Nuremberg the public library—founded by Conrad Kühnhofer in 1445—was, in 1538, deposited in the Dominican Monastery, where it still remains. It possesses more than 50,000 volumes of printed books, 900 of which are *Incunabula*. The MS. collection amounts to about 800 volumes, and includes many interesting illuminated manuscripts, with autograph works of Luther, Hans Sachs, the famous German poet, and Albert Durer. One of the volumes is a Latin Breviary of the middle of the fourteenth century, richly illuminated, presented, according to the French inscription, by Charles, King of France, to Madame the Queen of England. This, says Von Murr, was either Isabella, wife of Richard II. (1396), or Catharine, wife of Henry V., King of England. They were both daughters of Charles VI., King of France. An account of the MSS. and early printed books is given in the work of Von Murr, entitled, *Memorabilia Bibliothecarum Publicarum Nurembergensium et Universitatis Altdorfinae*, Nuremb. 1786–91, 3 vols. 8vo. Nuremberg also possesses three several church libraries, all of which were founded prior to 1625, and one of which—the Fenitzer-Dillherr Library—possesses at least 10,000 volumes. In 1852 the foundation of a new library, with reference especially to Germanic history, was laid by the liberality of the Baron Von Aufsess, and is, we believe, making progress.⁹

The Public Libraries of Hamburg are numerous and important. Those of chief note are the City Library and the Commercial Library. The former was founded in 1529, and now contains about 200,000 volumes of printed books, exclusive of a series of Dissertations, the number of which is nearly 20,000. The MSS. are about 5000.¹⁰ The Commercial Library dates from 1735, contains more than 40,000 printed volumes, and is unquestionably the best special collection of its kind in Europe. It has no MSS. of much importance, save on the history of Hamburg itself. On this subject there is a very valuable collection of books and documents, partly printed and partly MS. There is also an extensive collection of maps and charts.¹¹ The catalogue of the Commercial Library is according to subjects, and is printed up to the end of 1853.¹² The catalogues of the City Library remain unprinted. Its manuscript Alphabetical Catalogue fills 40 volumes in folio. Among the MSS. is an early *Homeri Odyssea* in Greek, on charta bombycina; a Latin *Æsop*, with curious drawings; the Gospels in Greek from Uffenbach's Library; and an interesting series of autograph letters of the German Reformers. Many valuable printed works might also have been specified, had the limits of this article permitted.

In Heidelberg, the present University Library dates from 1703, and now contains about 150,000 printed volumes;

¹ *Serapeum*, ut supra, p. 18.

² *Foreign Office Returns* of 1850, p. 377.

³ Dr Petzholdt (*Handbuch*, p. 404), after stating that the number of printed volumes at Wolfenbüttel has been repeatedly but erroneously said to be 270,000, and that of MSS. 10,000, inclines to assign to it about 200,000 of the former, and 5000 of the latter; but there is reason to think that even this is an over-statement.

Foreign
Libraries

50,000 Dissertations, and more than 3000 MSS.¹ Of the latter the most precious are those which had formed part of the ancient *Bibliotheca Palatina*, and which were restored under the circumstances we have narrated in our account of the Vatican Library. Among these are the famous Greek manuscripts of Xenophon, Thucydides, and the *Anthologia* of the tenth and eleventh centuries; Ottfried's metrical version of the Gospels, of the ninth century; and a volume of old German poems and romances. At Bonn, Breslau, Erlangen, Giessen, Halle, Königsberg, Marburg, and Treves, there are also valuable libraries.

V. HOLLAND.

Dutch Li-
braries.

There are many libraries in Holland; indeed almost every city has one; but the principal collections are the University Libraries of Leyden and Utrecht, and the Royal Library at the Hague. The University Library of Leyden was founded by William I., Prince of Orange, and is justly celebrated throughout Europe for the many valuable specimens of Greek and Oriental literature with which it abounds. To it Joseph Scaliger bequeathed his fine collection of Hebrew books; and it was further enriched by the learned Golius, on his return from the East, with many Arabic, Turkish, Persian, and Chaldaic manuscripts. In addition to these, it received the collections of Holmanus; and those—still more important—of Isaac Vossius and Ruhnken; the former, which had to be removed to Leyden from Windsor, contained a great number of valuable manuscripts, supposed to have once belonged to Christina, Queen of Sweden; and the latter, an almost entire series of classical authors, with a collection of manuscripts, amongst which are to be found copies of several that were subsequently consumed by fire in the Abbey of St Germain-des-Prés. A catalogue of this library was printed in 1716, with a supplement in 1749, both in folio.² In 1852 was published *Catalogus Librorum Manuscriptorum qui inde ab anno 1711, Bibliothecæ Lugduno-Batavæ accesserunt*, 4to. It describes 1015 articles. Many fine manuscripts might be noticed; in particular, a Virgil, an Italian transcript of the fifteenth century, illuminated with some large designs on coloured vellum; a volume of Monstrelet's *Chronicles*, in French, of the same age, with illuminations; the Psalter, illuminated, which, according to a French note, was made use of by St Louis in his childhood. It is apparently of the twelfth century (although, in the printed catalogue, assigned to the fourteenth), and written in England, for the English have that name in the calendar. There are various important Greek manuscripts; and among the printed books, the *Justiniani Institutiones*, 1468, and the *Apuleius* of 1468, upon vellum. There is also a copy of the Bible in Dutch, printed at the expense of Peter the First, at Amsterdam, 1721, 5 vols. folio, in capital letters. Half of each page is left blank, and some copies have the Russian text in parallel columns. Most of the copies are said to have been lost at sea. The library at Leyden is computed to contain upwards of 70,000 printed volumes, and 3000 volumes of MSS.,³ many of which, as we have seen, are equally curious and valuable.⁴ Of the public library at Amsterdam, the official statement is simply this, "The number of

printed books is 3150 [31,500?], and of MSS., 88; a printed Foreign catalogue appeared in 1796." Peignot drily remarked of Libraries this collection, many years ago, that it would be more useful if the books were arranged in better order and method.⁵

Of the University Library of Utrecht the precise date of Library of foundation is not recorded. But there is an entry in the the Uni- proceedings of the town-council which directs the bring- versity of ing together of the books of certain monasteries and col- Utrecht. leges, in order to the foundation of a Town Library, in 1581, fifty-five years before the establishment of the present University.⁶ On the conversion, in 1636, of the pre-existing "Athenæum" into a University, the Town Library was transferred to it. Catalogues were printed in 1670, in 1718, and in 1834-35. The last named is alphabetical, and in 2 vols. folio. The number of printed volumes has been estimated at 80,000, and of MSS. at upwards of 860, of which latter there is a written catalogue, well digested. These numbers, however, are but conjectural. The only direct statement we can trace is of 1835, at which date the number of printed *works*—not volumes—was 27,000,⁷ and that of MSS., 864. The MSS. are not of much general interest, being chiefly scholastic divinity, or ecclesiastical records connected with that district of Holland; but there is an ancient Greek Gospel of the ninth century, known as the *Codex Bezae Cantabrigiæ*, and a Latin Psalter of a still earlier period, with curious drawings. Among the printed books there is a splendid volume on vellum, *Missale Trajectense complectis multis missis rotivis nunquam antea impressis*, printed at Paris by Wolfgang Hopyl, 1515, and (from its having escaped the researches of Van Praet) probably unique. But the chief library in Hol- Royal lib- land is the Royal Library of the Hague. In its present shape rary at the and character this collection is little more than half a Hag- century old. But it includes what remained of the fine Library of the Stadtholders, the collection which had belonged to the States-General, and also some smaller libraries of corporate bodies. These were brought together in the *Mauristhuis*, after the flight of William V., and became the foundation of the Royal Library, which now possesses more than 100,000 volumes of printed books.⁸ Amongst these are comprised, (1.) nearly 1400 volumes from the early presses, about 500 of them Dutch; (2.) An Elzevirian collection, amounting to 690 volumes; (3.) Another special collection of the productions of the Aldine, Juntine, Stephanine, and Plantinian presses; and, (4.) A very curious collection of pamphlets on Dutch affairs, called *Bibliotheca Duncaniana*, after its former possessor. The MSS. amount to 2000. Amongst them is a fine Evangelary of the tenth century, which had formerly belonged to the ancient Abbey of Egmont, and a long series of liturgical and other devotional MSS. superbly illuminated. The historical MSS. are very numerous, and contain rich materials for the history of France, as well as for that of the Low Countries.⁹

VI. BELGIUM.

At Brussels there are two principal libraries; both of Belgian which belong to the government. The first of these is de- libraries. signated the Royal Library of Brussels, and was founded on that which formerly appertained to the house of Burgundy.

¹ Petzholdt, *ut supra*, p. 197.

² The quasi-official returns of 1835 referred to in the "Abstract" appended to Mr Disbrow's letter to Lord Palmerston of 6th Nov. 1849 (*Foreign Office Returns*, 1850, p. 300), says:—"Nearly 70,000 volumes, and 3000 MSS." Fourteen years had elapsed between the two applications for information, but the Dutch functionaries refer to the previous replies—themselves very perfunctory—without indicating change or addition of any kind.

Foreign
Libraries

Santander¹ has traced the history of this library through its varied fortunes, it having been successively exposed to the perils of fire, of interment, and of spoliation by French commissaries. Though it had been restored, in some degree, to its ancient splendour by the care of Count de Cobentzel, and of Prince Stahrenberg, minister-plenipotentiary of the Empress Queen, its prosperity was of short duration. For, when the French armies overran the Netherlands, and occupied Brussels, in 1797, Laurent, the representative of the people, caused seven waggon-loads of books and manuscripts to be taken from the Burgundian Library; and some time afterwards, Wailly, Leblond, and others, deputed to commit a second spoliation, selected about 200 manuscripts for the National Library at Paris. In 1797 a place was provided for the reception of the surviving books belonging to the Burgundian Library; and in 1798 the collection was enriched with all that was most valuable from the great dépôt of the Cordeliers, which was then broken up. But the fine library brought together by C. J. E. Van Hulthem, who died in 1832, has been the most important element in the composition of the present royal collection. It had been formed with great judgment, and was especially rich in Belgian history; nor is it undeserving of record that not a few of the volumes of this library had (in a very unusual manner) helped to *make* Belgian history, in some of its not least glorious pages; many a substantial and venerable folio of Van Hulthem's having done duty by way of breastwork for the Belgic volunteers during their obstinate conflict with the Dutch troops in September 1830. This collection amounted to 29,350 distinct printed works, in about 63,000 volumes, and to 1016 MSS. It was purchased by the government in 1837 for L.11,176, exclusive of incidental expenses.² There is a printed catalogue of it, well compiled by Voisin, in 6 volumes 8vo.³ Two years afterwards the conjoined collections, including that of the city, which had been public from 1794 (as that of Burgundy had been from 1772), were opened as the national collection of Belgium. Since that period the Brussels Library has, by systematic acquisitions, become still more extensive, and at present it contains nearly 203,000 volumes of printed books, and about 19,700 MSS.,⁴ each distinct work or article being counted. "Nothing," says a recent reader there, "can exceed the comfort of the reading-room."

The *Archives Générales du Royaume* form the second of the principal collections of Brussels. They unite the characters of a Library of MSS. and of a State Paper Office; the documents they contain extend from the twelfth to the nineteenth centuries; and in 1838 numbered 130,394, classified in fifty-seven divisions.⁵ The collection is of high historical importance, and has been well arranged by M. Gachard. The provincial libraries of Belgium are those of Antwerp, Bruges, Ghent, Liège, Louvain, Mons, Namur, Tournay, and Ypres, three of which (those of Ghent, Liège, and Louvain) are under the direction of the universities established at these places, whilst the others are under the superintendence of the local authorities. Of these provincial libraries, that of Ghent is the largest. It possesses of

printed volumes about 64,500 (of which 480 are *incunabula*), and of MS. volumes 630. Liège has also nearly 64,000 printed volumes, and 480 MSS. Louvain has about 62,000 printed volumes, and 302 MSS.; Tournay, about 27,700 printed, and 208 MSS.; Antwerp, about 22,000 printed, and 29 MSS.; Namur, about 17,700 printed, and 80 MSS.; Mons, about 16,400 printed, and 348 MSS.; and Bruges, about 12,000 printed, and 550 MSS.

Libraries

VII. HUNGARY.

Many fragments of that noble library, so rich in valuable manuscripts, which had been formed at Buda by the celebrated Corvinus, have been mentioned in our accounts of the several existing libraries that possess them.⁶ When this collection was dispersed, on the capture of Buda by the Turks, under Solymán, in 1526, Cardinal Bozman in vain offered the conqueror 2000 crowns to restore this part of the spoil. If no collection subsequently formed, up to the end of the last century, could lay claim to the title of a Hungarian national library, yet since 1804, by the liberality of Count Sczecheny, Pesth has become possessed of an assemblage of books, admirably chosen, fast increasing, and well deserving to be styled the library of Hungary. The books are entered alphabetically in the catalogue and supplements, and classed in the indices according to subjects.⁷ The National Library already contains about 185,000 volumes of printed books, upwards of 10,000 MSS., about 10,000 prints, and 5000 maps. Of the printed volumes some 36,000 are Hungarian books; about 20,000 others are works in foreign languages, but relate to Hungary, as does also the bulk of the MSS.⁸ Few libraries, it will be seen, can possess a better title to be termed "National."

Pesth has two other libraries, both of them important. That of the University owes its foundation to the celebrated Primate of Hungary, Peter Pázmány.⁹ From Tyrnau (the first seat of the University), it was transferred to Buda in 1777, and thence, seven years afterwards, removed to the other side of the river. In 1853 it possessed nearly 72,000 volumes of printed books, and 1510 MSS. The third library of Pesth is sometimes called the *Teleki Library*, and sometimes the *Library of the Hungarian Academy of Sciences*. In the Diet of 1826, Count Joseph Teleki, for himself and his brothers, presented to his fellow-countrymen the fine library of 30,000 volumes, which they had jointly inherited from their father. He also presented the sum of 5000 florins by way of beginning a maintenance fund. The example was followed with the old Hungarian spirit, and amongst the earliest imitators the illustrious name of Batthyány twice occurs; Count Casimir as the donor of 2660 volumes, and that of Count Gustavus as the donor of a library containing very nearly 30,000 volumes. A collection, especially rich in Hungarian history, was purchased in 1849 (5000 volumes); and, in 1852, Count Joseph Teleki increased the acquisition fund by a handsome contribution from the profits of his well-known historical work. In the following year the library possessed 70,660 volumes.¹⁰

Foreign
Libraries

VIII. BOHEMIA.

National
Museum
library of
Prague, &c.

In the city of Prague there is a library in connection with the National Museum, founded in 1818, consisting of more than 20,000 volumes of printed books, and 1200 volumes of MSS.¹ It is remarkable on account of the number of early works illustrative of Bohemian history and literature, from the first book printed in Bohemia (1462); and is open to all comers. Among other rarities, there is exhibited an original letter, signed "Johanes Hus, Magistre in Artibus, Sacre Theologie Baccalareus." The University of Prague has a fine library, which, in its Carolinian germ, dates, like the University itself, from the middle of the fourteenth century, and contains some relics of a library still older,—that of the Celestine Monastery of Oybin, in Upper Lusatia.² In 1621 both University and library were handed over to the Jesuits, and the latter, in subsequent years, was largely augmented by them. It became well known as the Clementine Library. Joseph II. restored the University to its independence, and vested in it the enlarged collection, which was further increased, first, by the books of dissolved monasteries, and subsequently by purchases. The University Library is well organized. When Mr Kohl visited it in 1841, he was shown a catalogue so arranged that the sum total of volumes could be added up daily. It was then 99,888.³ In 1848, it was 106,735.⁴ The present number of volumes is probably at least 110,000. There are many curiosities, and amongst them a superbly illuminated Hussite *Hymn Book*, the joint-stock production of the chief families and most eminent guilds of Prague. Prague has many other remarkable libraries, which we cannot find room even to enumerate. One, however, may claim a word. The Premonstratensian Monastery of Strahow has a library of great value, displayed in an apartment which, for splendour and elegance, has, it is said, scarcely its equal either in the Austrian States or in Germany.⁵ The number of printed volumes exceeds 50,000 (2000 *incunabula*), and that of MSS. is about 1000.⁶

IX. SWITZERLAND.

Libraries of
Geneva, &c.

In Switzerland there are several libraries eminently worthy of notice. We begin with that of Geneva. The celebrated Bonnard, prior of St Victor, having promised to bequeath his books for the foundation of a public library in Geneva, the council of that city resolved to act upon this promise, and in 1564 purchased the books which had belonged to Calvin, and in 1565 those of Peter Martyr. The progress of the library is detailed in the preface to an excellent *Catalogue de la Bibliothèque Publique de Genève*, by L. Vaucher, 1834, 2 vols. 8vo, when the library contained 31,000 volumes. Among Bonnard's books are several rare editions of the fifteenth century, such as Cicero's *Offices*, both editions, 1465 and 1466, on vellum (the first of them presented by Lord Stanhope); the *Livre des Saintes Angles*, the first book printed at Geneva, in 1478; the *Speculum Vitæ Humanæ*, printed in the Canton of Lucerne in 1472 or 1473; the *Mirouer du Monde*, Geneva, 1517, the only known copy printed on vellum. Among the manuscripts are several richly illuminated. Here also is that most interesting little volume, *La Noble Leyçon*, dated in the year 1100, and including two other treatises

and seven religious poems, in the language of the Vaudois; and, above all, the manuscripts of Calvin, and his correspondence, in many volumes, as described by Senebier in his *Catalogue raisonné des Manuscrits conservés dans la Bibliothèque de la Ville et République de Genève*, 1779, 8vo. The present number of volumes is about 47,000 printed, and 200 MSS.⁷ In 1852 Tutor Weizel made his valuable private collection of German literature publicly accessible. It is said to amount to 8000 volumes,⁸ and may probably become hereafter an important addition to the Town Library.

Zurich possesses two public libraries,—the Town Library and that of the Cantonal Schools;—the former with about 62,000 volumes of printed books, and 3500 MSS.; the latter with 27,000 printed volumes, and very few MSS. The Town Library was founded, jointly, by four young citizens in 1629, on their return from a European tour, which had made them acquainted with many such institutions. Amongst its MSS. the most remarkable volumes are the original letters of Lady Jane Grey and the English reformers to Bullinger, which have been printed for the Parker Society. In Berne the public library, which dates from 1548, contains 49,500 printed volumes, and 2303 MSS.⁹ Of the latter there is a catalogue by J. R. Sinner, in three vols. 8vo.¹⁰

In Basel the University Library possesses several early Greek manuscripts, such as a copy of the Gospels of the ninth, and the Epistles of the tenth century; the Acts of the Council of Basel (142), in several volumes; original unedited letters of Erasmus; also a copy of his *Morie Encomium*, with spirited sketches on the margins by Hans Holbein (some of them apparently retouched and injured), which have been several times engraved; various drawings by the old German masters, including several by the Holbeins, and a portrait of Edward VI. when a boy, marked "H. H." The total contents of the University Library amounted in 1853 to 75,000 printed, and nearly 4000 MS. volumes.¹¹ The library is more especially strong in the physical and mathematical sciences, in theology, and in the polite literature of Germany. According to the recent rate of increase, the number of printed books in this library must at present amount to at least 78,000 volumes.

The canton of Aargau acquired by purchase, in 1804, the valuable collection of General Zurlauben of Zug. The books of secularized monasteries served to augment the Cantonal Library thus begun, and it has also been occasionally increased by purchases. In 1846 it contained about 60,000 printed volumes, and 1200 MSS.¹² The Cantonal Library at Lausanne contains about 45,000 vols. of printed books,¹³ and, perhaps, 300 MSS. But for a long period, Lausanne possessed a literary treasure which had more powerful charms for British eyes than anything they could see in the public library. Few great writers mention their books so frequently or so fondly as does Gibbon; and it is scarcely credible that he would have left his beloved authors behind him with such slender precautions for their safety, had he departed from Lausanne under circumstances of less excitement and alarm than those of May 1793. Nor is it less extraordinary that, after its preservation for many years in an uninhabited house, his library became the property of another English author, who, to use his own characteristic words, "bought it to have something to read when he passed

Libraries

through Lausanne,¹ shut himself in it from morning till night during forty days, and then "dashed among the mountains," never to set eyes upon it again (although he survived his purchase a quarter of a century), leaving it still in a house which was usually untenanted.² At length, forty years after Gibbon had fled from Lausanne in hot haste, this precious collection was sold by auction: part went to America, part to the Cantonal Library. Other portions were scattered far and wide, carrying with them, however, traces of two names, suggestive of very different ideas: the one, a monument of what genius can accomplish when aided by self-denying labour; the other a monition, that vast wealth, unusual powers of mind, and refined tastes, may all centre in one man, and yet leave him at the end of a long life, a prodigal and worthless egotist.

X. POLAND

Libraries
of Poland.

Of Poland it may be said, in a bibliographical as well as political sense, *Stat magni nominis umbra*. The literary treasures of that ancient kingdom have gone to enrich its principal spoiler; and it is at St Petersburg rather than at Warsaw that we must seek for evidence of what it originally possessed. What is called the Royal Library at Warsaw is said not much to exceed 20,000 volumes, most of which are modern; but it contains a manuscript, in 3 folio volumes, with nearly 200 fine drawings, descriptive of the antiquities excavated at Velleia, between the years 1760 and 1765. The University of Warsaw, founded by the Emperor Alexander in 1816, had accumulated a library of about 150,000 volumes; but after the events of 1830 and 1831, every book or pamphlet in it conceived to be hostile to the Russian government was removed, and many scientific works have likewise, it is believed, been abstracted and sent off to St Petersburg. As late, however, as 1849, we find mention of this library as being "said to contain 150,000 [printed] volumes, and a great number of scarce and curious MSS."³ If this be not merely a repetition of preceding statements, it may suggest the idea that the two Warsaw collections have perhaps been united. (?) But it is a significant circumstance, that, although the Russian official returns of 1850 enumerate thirty-eight libraries in addition to those of St Petersburg⁴ (some of them containing less than 500 volumes), there is no mention of any library at Warsaw. The University of Cracow, founded by Casimir the Great in 1343, has a library said to contain about 10,000 MSS., amongst which is a Latin Encyclopædia, in a large folio volume, written by Paul of Prague in 1459, and nearly 50,000 volumes of printed books.⁵ But the most extensive and valuable collection that has ever existed in Poland was that which Count Joseph Zaluski and his brother had formed, and which, in 1747, was devoted to the public. The Zaluski Library, afterwards called the Library of the Republic, consisted of 300,000 volumes, including

upwards of 50,000 duplicates, which were subsequently disposed of; and by the sale of these, together with the losses sustained by various depredations, the collection was supposed, in 1791, not greatly to exceed 200,000 volumes. At length, in 1795, this library was unceremoniously seized by Suwarof, hastily packed up, and despatched to St Petersburg, to aggrandise the capital of the conqueror with the literary spoils of Poland.⁶

Foreign
Libraries

XI. RUSSIA.

To this act of spoliation the Imperial Library of St Petersburg owes, if not its existence, at least its first "acquisition" of importance. Nor is it needful to dwell upon dates. If, with Bacmeister, we even trace some beginnings of the Imperial Library as far back as the year 1714, we shall still find the sapling of like origin with the graft. The books of 1714 were seized during the invasion of Courland, just as the books of 1795 were snatched in the swoop on Poland. Nor does the courtly academical think fit to affect the smallest prudery about the matter. "It was thus," he says, "that Paulus Emilius, the conqueror of Perseus, carried to Rome that monarch's books—the first that were seen in the capital of the world. Thus Sylla, after subjugating Athens, gathered from Athenian books a library alike extensive and choice. Peter the Great followed in the footsteps of these great men."⁷ Could Bacmeister have foreseen the achievements of 1795, his vocabulary would scarcely have supplied words sufficiently eulogistic. Later writers, however, have sometimes thought it desirable to fortify Russian practice by modern examples. But the parallel limps. The French, when they conquered Italy and Belgium, stripped the libraries of those countries, indeed, of some of their choicest rarities. But the Russians, when they triumphed over the independence of Poland, carried off, in bulk, the largest collection of books which that country could boast of. The library thus seized had been built up with refined tastes and liberal sympathy. The library into which it was transformed has often been augmented with lavish expenditure; but the dominant spirit that has animated its management has been narrow, jealous, and servile. The one was free to all comers;⁸ the other has been open to everybody—who was in no respect obnoxious to the Russian police.⁹ In the space of forty-three years Count Joseph Zaluski had acquired, at his own expense, above 200,000 volumes. His brother, Andrew Zaluski, Bishop of Cracow, enriched this numerous collection, as well with the books bequeathed to him by the last descendant of John III., King of Poland, as with those which he collected from the libraries of his uncles, Andrew Olszofski, Primate of the kingdom of Poland, Prince Andrew Chrysostom, Bishop of Warmia, and Louis Bartholomew, Bishop of Plock; and after having joined to these the collection in his own cabinet, he transferred the whole, in 1742, to a house which

⁴ *Foreign Office Returns*, 1850, pp. 339, 340.

⁵ Petzholdt, *ut supra*, p. 218.

⁶ It seems almost too poetically fitting to be literally true (under existing circumstances), that the Zaluski Palace at Warsaw has been purchased by a wealthy Polish nobleman, the Marquess Wielopolski, for the establishment of a national library. Some of our readers, however, may remember to have seen the statement in the newspapers early last year (1856). What foundation there may have been for the assertion we do not know.

⁷ Bacmeister, *Essai sur la Bibliothèque de l'Académie des Sciences de St Petersburg* (1776), p. 47.

⁸ . . . "In ornamentum Patriæ, Civiumque suorum perpetuam utilitatem,

Publicam esse voluit:

Adolescentibus illicium, senibus subsidium,

Otiosis spectaculum, occupatis divitiolum,

Studiosis negotium,

Conditori gloriosum monumentum"—

Such were the words of the inscription on the Zaluski Library.

⁹ It would, however, be unjust to state thus much of truth as to the past, without adding that there is some reason to believe that under the present emperor, and under the able administration of Baron von Korff, as chief librarian, greater liberality is likely to characterize the future.

Foreign
Libraries

had previously belonged to the family of Danilovitch, and had probably come to him by inheritance. In 1747 he rendered it public, and settled an annual income or endowment for its support and increase. In the very year in which it was thus made accessible, we find it described as being already "a splendid, unequalled, and, in regard especially to its stores of Polish history, an inestimable library."¹ After the death of this prelate, Count Joseph Zaluski still further augmented it by the addition of a great number of volumes, and, by his will, made in 1761, bequeathed it, along with the house in which it was deposited, to the college of Jesuits at Warsaw,² in trust for the public. After the suppression of that order in 1773, it was placed under the care of the Commission of Education, and at last seized and carried off to St Petersburg in 1795, as already narrated. This transportation being made by land, and along roads which the late season of the year rendered almost impracticable, many boxes of books suffered from the inclemency of the weather, others were broken or damaged, and the works which they contained spoiled, misplaced, or separated, and the sets broken. The collection was conveyed to the imperial cabinet in two convoys, and after the inventory had been completed on the 23d of February 1796, it was found that the collection still amounted to 262,640 volumes, and 24,573 prints. This library comprised in general all the best works, up to the middle of the seventeenth century, in the sciences, the arts, and the belles-lettres. The theological, and, after it, the historical and literary branches, were the most considerable. The theological department alone comprehended above 80,000 volumes. It was also rich in topography, especially in the histories of towns; and the literary branch included a precious collection of classical books and works on bibliography; but the departments of philosophy, mathematics, physics, travels, and antiquities were very incomplete.³ Such was the foundation of the Imperial Library at St Petersburg. But for the spoils of Poland, that collection, instead of now ranking in the first class, would scarcely, perhaps, have been entitled to a place in the third.

This library, augmented by various other collections, and by purchases both extensive and systematic, amounted, in 1849, to 451,532 printed volumes, and 20,689 volumes of MSS.⁴ Of late years, the official reports have been annually published in the *St Petersburg Zeitung*, and reprinted in the *Serapeum*. We gather from them that in some years (as in 1855, for instance, notwithstanding the war), the accessions, from all sources⁵ together, have reached 15,000 volumes.⁶ Probably, for the entire period from 1849 to 1857, they will have averaged 8000 volumes a-year. On this basis the present total would be 519,500 volumes and about 21,000 MSS. Its management is detailed at length in the Appendix to the *Report of the Select Committee on the British Museum* (p. 449, *et seqq.*). Supplementary information of later date will be found amongst

the Foreign Official Returns appended to the *Report from Foreign Select Committee on Public Libraries* of 1850; to both of which we refer.

The Library of the Academy of Sciences at St Petersburg Library of the Academy of Sciences. was drafted from that early "Imperial Library," the origin of which we have already narrated; and the bulk of which Catherine I., in 1726, presented to the newly-instituted society. It continued to increase, by the bounty and by the enterprise of succeeding czars. Bacmeister (whom we know already) has minutely chronicled its progress: after telling of the many collections it had successively absorbed, he breaks into this philosophical reflection,—“It is an astonishing thing that war, which everywhere else has been fatal to the sciences, has in Russia been advantageous to them. It was war that favoured the first establishment of our library, and it is to war that we are indebted for the chief additions that have been made to it.” But, since Bacmeister's days, other sources of augmentation have assisted its growth. In 1802, for instance, it received an important addition in the library and cabinet of Count Boutourlin, purchased by the Emperor Alexander. It is also entitled to a copy of every book printed within the Russian dominions. This collection contained, on the 1st January 1849, a total of 112,213 volumes (including MSS. as well as printed books), of which 24,933 were Russian, and 87,280 foreign. There were besides 6688 printed books and MSS. set apart in the "Asiatic Museum" of the Academy.⁷

The third public library of St Petersburg is that of the "Roumianzoff Museum," which became a public establishment in 1827. It contained, in 1849, 32,258 printed volumes, 965 MSS., 4620 prints, and 590 maps, &c.⁸ The Imperial Private Library is in the Palace of the Hermitage. It includes the Library of Diderot, purchased by the Empress Catherine in his lifetime, with permission to the vender to become its usufructuary for the remainder of his days; and also a considerable collection of the papers of Voltaire. It is a splendid library of more than 80,000 printed volumes,¹⁰ besides its fine MSS.; of the Voltairian portion of which M. Léonzon-Leduc has given an excellent account in the report above quoted.

XII. DENMARK.

There are three public libraries at Copenhagen, viz., Libraries the King's Library, the University Library, and Classen's at Copenhagen. Library. The Royal Public Library of Copenhagen dates its first commencement from the middle of the sixteenth century. In 1665 Frederick III. established it in its present building, and largely improved the collection. It now contains—according to the official reports—nearly 408,000 volumes of printed books, and about 15,000 MSS.¹¹ The University Library was originally founded prior to 1500;

¹ Janozki, *Nachricht von denen in der Hochgräflich Zaluskischen Bibliothek sich befindenden raren Polnischen Büchern* (Dresd. 1747, 8vo), p. 5.

² "The celebrated Library of Zaluski at Warsaw," says Denis, in his *Introduction to the Knowledge of Books*, "was opened to the public in 1747. It must contain at present near 300,000 volumes. Benedict XIV., in 1752, issued a bull of excommunication against those who should dare to commit depredations on this library; but, notwithstanding, many books were carried off, particularly during the late troubles. In 1747, the laborious librarian, Janozki, gave notices of the rare books printed in Polish; and, in 1752, he published a catalogue of the manuscripts in this library. After the death of its founder, the Bishop of Kiev, the king and the commonwealth took possession of this treasure, in spite of the attempts made by the heirs to retain it." (Denis, *Einleitung in die Bücherkunde*, Wien, 1777, th. i., p. 184.)

Foreign
Libraries

was destroyed by fire in 1730; and soon afterwards restored. It now contains nearly 154,000 printed, and 4000 MS. volumes. Classen's Library contains about 30,000 printed volumes, but possesses no MSS. These libraries, consisting of upwards of 600,000 volumes, printed and MS., are accessible to all respectable householders, and likewise to strangers introduced by such; and the books are, besides, under certain restrictions, allowed to circulate. The King's Library is general, and about equally complete in all the branches of human knowledge. The University Library is also to a certain extent general, but the main body of the collection has been made chiefly with reference to academical education. Classen's Library consists principally of books of geography, travels, natural history, and agriculture. The administration of these libraries seems to be both economical and efficient, and to be conducted solely with a view to public utility, which, in this case, means public instruction.¹ Of the principal catalogues of those Danish libraries we give a list below.²

XIII. SWEDEN AND NORWAY.

Royal Li-
brary, &c.,
of Sweden.

The public libraries in Sweden are, (1.) the Royal Library, situate in the northern wing of the king's palace at Stockholm; (2.) the library called *Benzelstjerna-Engeström*, founded by private individuals, but to which admission is readily granted on recommendation. These are in the capital. The Royal Library, which was founded by Gustavus Vasa about 1540, and enlarged by the liberality of succeeding sovereigns, contains about 96,000 volumes of printed books, with nearly 4000 MSS.,³ besides 16,500 charters and deeds, and is open to the public every day excepting Saturdays, Sundays, and holidays; books are lent out on respectable recommendation. The Library of *Benzelstjerna-Engeström* contains about 14,500 volumes of printed books, and 1200 volumes of MSS., rich in materials for Swedish history.⁴ Besides these, there are libraries attached to the different academies, which are also accessible. The number of provincial libraries in Sweden, including those of the Universities of Upsal and Lund, is nineteen. That of Upsal, which was founded by Gustavus Adolphus, is the largest in Sweden, and contains more than 135,000 printed volumes, with nearly 7000 MSS.⁵ A catalogue of the collection, by Professor Aurivilius, was printed in the year 1814, in 2 vols. 4to. The Library of Lund was founded at the same time as that university (1671) by Charles X., and possesses upwards of 70,000 printed volumes, and 2000 MSS.⁶ These libraries are supported and increased by an annual grant from the state, and by a fee paid by each student on entering the universities. In those provincial towns where large public schools, called *Gymnasia*, are established, there are also small libraries. These collections, which have been founded by private individuals, are kept up much in the same way as those belonging to the universities.⁷

Libraries in
Norway.

At Christiania, in Norway, the Library of the University contains about 115,000 printed volumes, and 600 MSS.⁸ It was founded, in 1811, upon a donation by the King of

Denmark of many thousand volumes of duplicates selected from the Royal Library at Copenhagen, when the extensive and valuable collection of Count Suhm was acquired.

Foreign
Libraries

There are six other libraries of some importance in Norway,—two of which are in the capital,—besides a very large number of school and village libraries. Of the former the most extensive is that of Trondheim, counting 26,000 printed volumes, and 800 MSS. The two smaller Christiania libraries have each of them about 12,000 printed volumes. That called *Deichman's Library*, possesses also 320 MSS.⁹

But the MSS. at Upsal, and those at Stockholm, are almost the only MSS. in the kingdom of Sweden and Norway which possess interest of a high order for strangers, as well as for natives. The Upsal collection includes the famous *Codex Argenteus*, containing the Gothic Gospels of Ulfilas. It was amongst the spoils seized by the Swedes at the storming of Prague, in 1648; and after passing successively through the hands of Queen Christina, of Isaac Vossius, and of the Count de la Gardie, was presented by the latter to the University of Upsal. It is, and in modern days has always been, imperfect; but ten leaves of it are said to have been recovered at the end of 1856. It has been recently and ably edited by Dr Massman. Amongst the surviving treasures of Stockholm (the Royal Library suffered severely by fire in 1697), is a golden book which has had even stranger vicissitudes than the silver book of Upsal. The Latin Evangeliary, which is called *Codex Aureus*, bears an inscription in Anglo-Saxon, recording its rescue "from a heathen war-troop, with our pure treasure," by "Alfred, and Werburgh, his wife." Long after this incident it found its way to Madrid, where, in 1690, it was purchased by Sparvenfeldt, and carried into Sweden. Another biblical MS. (*Codex Giganteus*) contains nearly all the Old Testament, much of the Apocrypha, all the New Testament, except the Pauline Epistles and the Apocalypse; the greater part of Josephus; and a strange treatise on magic, adorned with a gilded portrait of the arch-enemy. Here is also a most curious English medical MS., apparently of the fourteenth century, somewhat after the fashion of the *Regimen Sanitatis* of the famous School of Salerno. Appended to this part of the *Codex*, which is metrical, are various prescriptions and clinical memoranda, which have sometimes led to its description as a physician's case-book. There are other choice MSS., which cannot here find mention.¹⁰ Of the Upsal Library, there is a printed catalogue up to 1814,¹¹ since continued in MS. Of the MSS. given by Sparvenfeldt, a catalogue was printed in 1706.¹² Of the Oriental MSS., the first part of a catalogue, by Toruberg, was printed in 1849.¹³

XIV. TURKEY.

Oriental libraries are, usually, but small collections, the contents of which are little known to Europeans. Their general character, however, will be most satisfactorily indicated by the description of some of them.

At Constantinople there are, within the walls of the

¹ App. to the *Report on the British Museum*, p. 483.

² *Codices Orientales Bibliothecæ Regiæ Havniciæ*, &c. Hafn. 1846, 4to; *Description des Manuscrits François du Moyen Age de la Bibl. Roy. de Copenhague*, par Abrahams, Copen., 1844, 8vo; *Catalogus Bibliothecæ Thottianæ* [by Ebert and Ecard] Havniciæ, 1789-95, 12 vols. 8vo. Part of the splendid collection of Thott (who had amassed 121,945 printed volumes—6039 of which were printed anterior to 1530—and 4154 MSS.) was added to the Royal Library by bequest, and part by subsequent purchase. The catalogue is so good, that Brunet has said of it, if it be not one of the choicest, it is certainly one of the most useful books, which a bibliographer could put into his working collection. Of the Oriental MSS. of the University Library, a portion is described in Westergaard's catalogue, entitled, *Codices Indici Bibliothecæ Universitatis Havniciæ*.

Foreign
Libraries
of Constantinople.

Seraglio, two libraries, which were founded respectively by Achmed III. and Mustapha III., and enriched with books acquired by themselves or their successors. These libraries do not appear to contain more than 6000¹ volumes, and are seldom increased by purchase, but occasionally by donations made to the sultan by his grandees, or by confiscations of the effects of public officers, amongst which books are sometimes to be found.² Much uncertainty has prevailed, and many erroneous reports have been circulated, respecting the contents of these libraries. The Abbé Sevin, who arrived at Constantinople in December 1728, failed to obtain admission into the Sultan's Library; and, deterred by the assurances he had received, that Amurath IV. had caused all the Greek MSS. to be burned, he deemed any further research or inquiry to be hopeless; whilst succeeding travellers, relying on statements of a different kind, have—as we had occasion to notice in a preceding part of this article—confidently asserted that in these libraries were still preserved the ancient collections of the Greek emperors.³ More fortunate than his predecessors, however, Toderini, after three years' unremitting attempts during his residence at Constantinople, found means to procure transcripts of the catalogues of the libraries in the Seraglio, through the instrumentality of a page who clandestinely copied a few lines every day.⁴ From the inquiries of the learned Abbate, it appears that the merits of these collections had been greatly exaggerated. The libraries of the Seraglio are much inferior to some of those which are open to the public. Commentaries, explanations, marginal notes, and other writings on the *Koran*, form the subjects of the largest portion; to which succeed treatises on jurisprudence (also accompanied with notes and commentaries), on philosophy, logic, astronomy, arithmetic, medicine, and ethics. The historical works are few in number, and chiefly relate to the Ottoman empire. There are some MSS. in the Greek, Latin, and other European languages; but no traces whatever have been discovered of the lost decades of Livy, of the writings of Homer or Tacitus, or of those parts which are deficient in the works of other ancient authors.⁵

Besides those of the Seraglio, Constantinople possesses thirty-nine public libraries,⁶ all varying in extent, but more or less noticeable for the number and value of their manuscripts, which are neatly bound in red, green, or black morocco. The Mohammedans have a peculiar method of indorsing, placing, and preserving their books. Each volume, besides being bound in morocco, is preserved from dust in a case of the same material; and on it, as well as on the edges of the leaves, the title is written in legible characters. The books are placed one upon another in presses ornamented with trellis-work, and are disposed along the wall, or in the four corners of the library. To facilitate literary researches, each library is furnished with a catalogue, containing the title, and giving a short account of the subject of each volume. Theology, including the *Koran* and *Commentaries* thereon, jurisprudence, medicine, ethics, and history, are the sciences chiefly cultivated by the

Osmanlees. The books are usually written with the greatest care, on the finest vellum; the text of each page is inclosed in a highly-ornamented and gilt frame work; the beginning of each chapter or section is splendidly illuminated; and the prices of the manuscripts vary in proportion to the beauty of the characters.⁷ Under the reign of the late Sultan Mahmoud, the introduction of European discipline, and, to a certain extent, of European customs and manners, has paved the way for still more important innovations. Recent events must also greatly facilitate the introduction of European knowledge and civilization, and the ultimate subversion of those fanatical prejudices, which, when fostered by ignorance and matured by superstition, have ever presented the most formidable obstacle to the improvement of nations.

The Library of the Convent of Mount Sinai was found by Mr Burckhardt to contain a great number of Arabic manuscripts, and some Greek books; but the former proved to be of little literary value; and of the latter, Burckhardt carried away two beautiful Aldine editions, a Homer and an *Anthology*. The priests refused to show him their Arabic memorandum-books previous to the fifteenth century; but from those which he was permitted to inspect, he copied some very interesting documents concerning the former state of the country.⁸

Foreign
Libraries

(3.) AMERICAN AND COLONIAL LIBRARIES.

I. UNITED STATES OF AMERICA.

Scarcely any country in the world has made, within a period of ten years, such rapid strides in the provision and improvement of libraries, freely accessible, as have the United States, since the year 1847. Libraries, indeed, had been among the objects of early solicitude to the colonists; but the work that lay nearest their hand was too stern and too urgent to admit of much more being done in this direction than was plainly and immediately educational. Collegiate libraries were cared for from the first. School libraries grew up quietly as incidents of school organization. Men met together to form proprietary libraries of various kinds, as soon as the comparative completion in the older parts of the country of the rough pioneer work gave them a little breathing time, just before the outbreak of the revolutionary war. When that fierce strife came, libraries were not infrequently turned into barracks, or into military hospitals; nor can it be at all a matter of surprise that occasionally books found their way into knapsacks (usually of British manufacture), and suffered an eventual metamorphosis into grog.⁹ In more peaceful times the old libraries were sought for and furnished up. Accessions were made, and a systematic literary intercourse with Europe was established. Private libraries, too, were formed, with improving taste, and with a liberality according well with the great wealth of many of their owners. Two classes of libraries, however,—each of them the most important of all within its own sphere,—have sprung up only in recent

Libraries
of United
States.

¹ White, *Three Years in Constantinople*, 2d edit., 1846 (vol. ii., pp. 182–196). Mr White affirms distinctly that the librarian's own statement of the larger of these two Seraglio Libraries, made to himself in June 1842, was, that it contained but 4440 volumes. It had contained within his memory 6100, but the late sultan had removed some of them to another collection. D'Ohsson has stated that these Seraglio Libraries contained in his day 16,000 volumes. Recent writers have put them at 20,000. The returns sent by Lord Redcliffe to Lord Palmerston, in 1850, do not contain the precise number of volumes in any Turkish library, but say generally that the largest of them "do not contain more than about 4000 volumes." (*Foreign Office Returns* of 1851, p. 50.)

² D'Ohsson, *Tableau général de l'Empire Ottomane*, tom. ii., pp. 487–494.

³ It is not a little singular that Dr E. D. Clarke has made no mention whatever of the libraries of the Seraglio, although he has given a detailed, and, upon the whole, picturesque description of its interior.

⁹ MacMullen, *The Past, Present, and Future of the New York Society Library* (1856), p. 5.

American days. Of the first class, the Astor Library at New York may be considered a type; and of the second, the Free Public Library of the city of Boston. Our retrospect of the growth and progress of American libraries, from the foundation of that of Harvard College in 1638, to the establishment of the Boston Free Library in 1852, must be compressed into very narrow limits; but will be best arranged in the order indicated by their actual succession. We begin, therefore, with university or collegiate libraries.

Almost the entire progress made by Harvard Library between 1638 and 1764, was cancelled by the disastrous fire which occurred in the college buildings early in the last named year. By that accident, about 5000 books were destroyed, and some pleasant links which visibly connected the memories of many British worthies with the growing American university were sundered. Among the burned books were many that had been given by Kenelm Digby, by John Maynard, by Lightfoot, by Gale, and by Bishop Berkeley. Vigorous efforts were soon made to form a new library. The legislative bodies of other States, as well as that of Massachusetts, contributed. Friends in England, amongst whom Thomas Hollis was pre-eminent, gave zealous help. But the war interposed serious obstacles; and even in 1790, the collection did not muster more than 12,000 volumes. They were well chosen; and have now grown into a library, which (including its ancillary or special collections, such as those of Divinity and of Law) numbers at least 83,000 volumes, and is steadily increasing. There is a good printed catalogue,¹ and the library is freely accessible for literary purposes. The Library of Brown University, in Rhode Island, ranks next. Its first beginnings date from 1768.² It now contains about 30,000 volumes; exclusive of the students' libraries, which number nearly 12,000 more. Yale College Library is somewhat older than the college itself; it being recorded, that at the second of the preliminary meetings, in 1700, each of the ten founders brought with him some books, and placing them on the table, said,—“*I give these books for the founding of a college in this colony.*” But the real cornerstone of the library was laid by Bishop Berkeley thirty years later.³ He sent over the finest collection of books that had then been seen in America; and it is owing to his influence that Yale College can show in her Donation-Book the names of Burnet, Kennet, Bentley, Halley, Newton, and Steele. This collection has grown to somewhat more than 27,000 volumes; besides three subsidiary students' libraries, containing, in the aggregate, 33,000 volumes more. The Library of the University of Virginia dates but from 1825, and was selected and originally arranged by Jefferson. It now numbers upwards of 21,000 volumes. There are more than 100 other college libraries, most of which are yet in the cradle, but give good promise of growth. The aggregate number of volumes in all the libraries of this class is estimated to exceed 650,000; exclusively of the students' libraries, which amount, nominally, to nearly 300,000 volumes in addition; but collections of this kind must obviously require large deduction for wear and tear.

The most valuable of the proprietary libraries is also the oldest of them; “and was,” says Benjamin Franklin, “my first project of a public nature. I drew up the proposals,

... and procured subscribers.” This was in 1731. “We afterwards,” he continues, “obtained a charter [1742], the company being increased to one hundred; this was the mother of all the North American subscription libraries. It is become a great thing itself, and goes on increasing. These libraries have improved the general conversation of the Americans; have made the common tradesmen and farmers as intelligent as most gentlemen from other countries, and perhaps have contributed, in some degree, to the stand so generally made throughout the colonies in defence of their privileges.”⁴ James Logan, the friend and counsellor of William Penn, had formed a valuable collection of books, and had given them to trustees in Philadelphia for public use. Another collection formed in England by his brother served to augment the former; and, in 1792, an act of the Pennsylvania legislature conjoined the Loganian collection with the library founded by Franklin. It now, therefore, under the title of “Library of the Philadelphia Library Company,” combines the characters of a public and of a subscription library; as a reference collection, it is freely accessible; as a lending collection, subscribers only may borrow books. The United Libraries contained in April 1856, 64,195 volumes.⁵ There is a very good classified and printed catalogue, up to 1835 (2 vols. 8vo), which has won the merited commendation of Brunet. (“We consider,” he says, “this catalogue a good model for our own public libraries.”⁶) And we have before us some proof-sheets of a third volume, on the same plan, which contains all the added books up to April 1856. Next in rank comes the Library of the Boston Athenæum, a very choice assemblage of books, and better stocked with foreign scientific literature than are most American libraries, amounting in 1857 to more than 60,000 volumes; and enjoying the eminent distinction of possessing a portion of the library of Washington. The third place belongs to the Mercantile Library of New York, commenced in 1821, and which, under the vigorous management of Mr S. Hastings Grant, had grown, on the 1st August 1856, to 47,082 volumes;⁷ of this collection too, there is an excellent catalogue, or index, on the alphabetical plan. The Mercantile Libraries of Boston, Cincinnati, and St Louis are of subsequent date, and contained, respectively, in 1856, 18,000,⁸ 16,423,⁹ and 12,840 volumes.¹⁰ The library of the American Antiquarian Society at Worcester contains the curious collections of its founder, Dr Isaiah Thomas, the historian of American printing, and also those of the Mather family. It now amounts to nearly 21,000 volumes. The New York Society Library was founded about 1700, by the Rev. John Sharp, the English chaplain of Lord Bellamont, then governor of the colony, and was augmented by a small collection bequeathed by an English rector thirty years afterwards. It now contains upwards of 40,000 volumes of printed books, and a few MSS.¹¹

The earliest of the State libraries is that of New Hampshire, founded at Concord about 1770. It now contains little more than 7000 volumes. Ohio has a State library, founded in 1817, with between 15,000 and 16,000 volumes. That of New York, at Albany, is the largest and best selected of all the State libraries. It dates but from 1818, and was long an inconsiderable collection. The energetic administration of the late Dr J Romeyn Beck

American
Libraries.

raised it rapidly to an important position; and it now contains 43,634 volumes of printed books,¹ and some valuable MSS., chiefly relating to American history; amongst them many early colonial charters and other public documents; the papers of Sir William Johnson and of Governor Clinton, and a curious series of letters relating to the affair of Major André. The remaining State libraries, twenty-six in number, range from 3000 up to 17,000 volumes, and contain, in the aggregate, nearly 200,000 volumes. These are of course, in the main, not only political, but Americo-political in character; and are especially intended for the furtherance of public business.

Library of
Congress at
Washing-
ton.

The first Library of Congress was destroyed by the British army in 1815. The second library was founded on the basis of that of President Jefferson, and was partially destroyed by fire in 1851. At the time of this calamity it contained more than 50,000 volumes, but of these about 20,000 were saved,—including much of the Jefferson collection, which was strong in American history,—and became the nucleus of a third library. At the beginning of 1854, 20,000 volumes had been already acquired, chiefly by purchases, to meet which appropriations have been made by Congress, amounting to about L.17,000. Early attention was wisely given to the acquisition of,—(1.) The long sets of important periodicals; (2.) The great antiquarian and scientific works of the Champollions, Rosellinis, Kingsboroughs, and Humboldts; (3.) Valuable and rare works on American history. At present the collection, which is not yet definitively arranged, must number between 60,000 and 70,000 volumes.

Astor li-
brary at
New York

America cannot be said to have possessed any great library, formed with especial view to the wants of the higher classes of students, until the bequest of John Jacob Astor (of "four hundred thousand dollars, out of my residuary estate, to the establishment of a public library in the City of New York") laid a very substantial foundation for such an one, in the year 1839. The testator died nine years afterwards, and his trustees were incorporated in 1849.

Their first proceeding was to select a librarian,—indeed, one had already been virtually selected by Mr Astor's own foresight,—and to send him to Europe (with large powers and wide discretion) for the purchase of books. Dr Cogswell acquitted himself of his task in the manner in which it had been foreseen he would perform it. He is now at the head of a well-chosen library, gathered from the best markets of England, France, Italy, and Germany, already numbering between 95,000 and 98,000 volumes; and lodged in a handsome and fire-proof building—Florentine in style—which is capable of holding, perhaps, three times the number. A sum of 180,000 dollars (L.37,500) was originally invested as a maintenance fund, and has since been increased. Liberal donations in aid of the library have also been received from Mr W. B. Astor, son of the founder.² The library is open to all comers as a library of reference, and is open to nobody as a lending library, so that students are certified that all books which the library possesses will be found within its walls.

Smithson's
library at
Washing-
ton.

The Smithsonian Institution at Washington possesses a library of about 15,000 volumes, the majority of which have accrued either by gift or by exchange for its publications. Founded, as will be remembered, by the contingent bequest of James Smithson, an Englishman (. . . "In case of the death of my said nephew without . . . children, . . . I then

bequeath the whole of my property . . . to the United States of America, to found at Washington, under the name of the Smithsonian Institution, an Establishment for the increase and diffusion of knowledge amongst men"),³ it was incorporated in 1846, and its name and publications have already become familiar throughout Europe. When the contingency occurred, the money was put to interest, so that, at the date of the charter, the fund amounted to nearly L.160,000. Great diversity of opinion prevailed as to the character of the appropriation which would best carry out the testator's purpose, and most redound to the honour of the United States. Eventually it was determined that the plan should include,—(1.) publications, especially such as should add to science; and, also, (2.) a library and museum. But hitherto the first part of the plan has been an Aaron's rod to the second part.

American
Libraries.

The first of those Free City Libraries, which bid fair to be worked out in the United States with true American energy and thoroughness, was that of Boston, organized in 1852 by the city government (by an ordinance of the 14th Oct.), but substantially founded on 5th August 1850, by Mr John P. Bigelow, Mayor of Boston, who then diverted a subscription of 1000 dollars, intended to be expended on some mark of the respect of his fellow citizens for himself, towards "the establishment of a Free Library;" and who had already received a present of French books, through the agency of M. A. Vattemare; and presents of American books from Edward Everett, and from Robert Winthrop, a descendant of the founder of the Commonwealth of Massachusetts.

Free City
libraries.

To this beginning Mr Joshua Bates brought a first contribution of 50,000 dollars (L.10,416), and a second contribution of an extensive series of books, purchased in Europe expressly for the library. Mr Jonathan Phillips gave 10,000 dollars (L.2083) to be invested as a book fund; Mr Abbott Lawrence, an active promoter of the enterprise, bequeathed a like sum at his lamented decease. This remarkable liberality was worthily met by the city authorities. The library was opened for public use in 1853, and now contains about 25,000 volumes. On its committee appear the names of Everett, Ticknor, and Story, in whose report it is described as "intended to furnish . . . the opportunity of completing that education of which the foundations have been laid in the public schools."⁴

The small town of New Bedford quickly followed the example of Boston. Its library is now in the fourth year of its existence, and has nearly 10,000 volumes. In the *Fourth Annual Report*, the trustees thus express themselves,—“A Free Public Library is the crowning glory of the system of public education, which has been, from our earliest history, the pride of Massachusetts. . . . No act of the municipal authorities has ever met so universally and deeply the approbation of the people.”⁵

The most noticeable libraries of the British colonies in America are those at Quebec and Montreal. Both are still small, but are progressive; and the legislature of Lower Canada has recently taken steps for their improvement and extension. In Upper Canada there is nothing which deserves to be called a public library. Even the collection which belongs to the legislature of that province is utterly neglected. “For nearly twelve years,” says Mr Mackenzie, “in several sessions of the provincial legislature, I made

American Libraries. repeated efforts to improve the library, . . . but the council refused."¹

II. BRAZIL AND MEXICO.

Libraries of Brazil,

and of Mexico.

In the Brazils the most important collection is that in the "National Public Library" of Rio de Janeiro, said to amount to 70,000 printed volumes, and 851 MSS. When John VI. carried to Brazil the Royal Library of the Ajuda, it included 4000 MSS., but these went back to Portugal on the declaration of independence. Mexico has three libraries in its capital (1. *Cathedral*; 2. *University*; 3. *Gregorian*), with about 12,500, 10,000, 7000 printed volumes; and 500, 600, 200 MSS. respectively; and also a public library at Puebla, founded by Bishop Palafox, with about 25,000 printed volumes.

III. INDIA.

Indian Libraries.

Of the libraries in India, whether composed of European or of native works, the want of information sufficiently to be relied on prevents us from attempting to give many details. The following account of the largest library at Goa, that of the Augustinian monks, extracted from the Diary of Sir James Mackintosh, is now of bygone years, but is curious enough to be worth quoting. It was certainly by no means a flattering description. "The books," he says, "are about 10,000; chiefly Latin and Portuguese, with a few Spanish, a very few Italian and Greek, no French, and of course no English, and none of any other language. There are not above twenty printed after the close of the seventeenth century. There are a few bad editions of classics, but not a complete edition even of Cicero himself: a great many schoolmen, casuists, and canonists, with some jurists: very little history, scarcely any of modern times, except a little Portuguese; about ten volumes of Portuguese and Spanish poetry; no morals, but as the handmaid or rather slave of superstition; no politics, no political economy, . . . no astronomy, no chemistry, no zoology, no botany, no mineralogy, and no book even on mathematics, but Euclid. I did not know before that the world had produced 10,000 such useless and pernicious books, or that it had been possible to have formed a large library, with so curious an exclusion of whatever is instructive or elegant."² At the different presidencies, and in some other parts of British India, collections, more or less extensive and valuable, are in course of formation; but they have not been particularly described. Of the native libraries of India we know as little. That of Tippoo Sahib, which fell into the hands of the British when his capital was taken, consisted of nearly 2000 volumes, many of them highly ornamented. *A Descriptive Catalogue of the Oriental Library of the late Tippoo Sultan of Mysore*, by Charles Stewart, was printed at the University press, Cambridge, 1809, 4to. With the exception of some select manuscripts presented by the East India Company to public libraries in Great Britain, these Mysore MSS. were deposited by the Marquess Wellesley in the College of Fort William, then newly established. There has recently appeared an elaborate *Catalogue of the Arabic, Persian, and Hindustani Manuscripts of the Libraries of the King of Oudh*, by Dr Sprenger, printed at Calcutta, 1854, 8vo. In the preface to this work, after having described the value of the collection, and the neglect into which it had fallen, Dr Sprenger remarks that, unless the travelling Orientalist who may hereafter visit the collection, should chance to be a zoologist as well, it will be prudent for him to poke with a

stick into the boxes in which the books are kept, before putting his hand into them. He illustrates the other departments of library economy, as practised at Lucknow, by observing that the "King's people" have long been accustomed to count the volumes periodically, but without any regard to their contents or character. So that the numbers do not diminish, the superintendents take no note of any changes in the books. "I have heard," he adds, "that a late librarian sold in one week 1100 rupees worth of books to provide funds for the marriage of his daughter."³ At Calcutta there is a good public library,—freely accessible for consulting purposes,—which contained in 1848, upwards of 20,000 volumes, and now contains probably 25,000.⁴

Indian Libraries.

The subjoined statistical table gives a comparative view of the numerical contents of the several libraries which have been referred to in the course of this article, those of private persons only excepted, and suggests a remark or two, with which our historical survey may fitly close. Had such a table been appended to the article "LIBRARIES" in the last edition of this work, the comparative place in it of Great Britain would have been far less creditable than it now is. In point of magnitude, our national library would have figured as tenth instead of second in the scale. In point of accessibility, almost every considerable library in this empire would have shown disadvantageously when compared with many libraries in France, with some in Italy, with nearly all in Germany. In respect to the number of libraries, of importance enough to subserve systematic study and research, our position would have been in direct contrast to the wealth, the extent, the quiet, the freedom, and the literary glory of Britain. If, indeed, our table had been so stretched as to include *private* collections, the list would have worn a different aspect, but (with a small number of honourable exceptions) its additional entries would no more have presented means of gratification to the mental appetites of the scholar, than the extension of his sumptuous bill of fare would have charmed the palate of the immortal Governor of Barataria, whilst he was under the wand of Dr Rezio de Agüero. As it now stands, in 1857, the number, extent, and accessibility of British libraries show a large measure of progress, but a measure which should rather be stimulating than satisfactory.

The main *desiderata* in this respect, as the matter shapes itself to us, seem to be,—(1.) Such a revision of the regulations of existing libraries, and, above all, of those of libraries which in some form or other derive national aid,—either directly from the public purse, or indirectly by contributions levied on authors and publishers,—as shall ensure the largest amount of public service consistent with safety and good order. (2.) The preparation and printing of thorough catalogues of the principal libraries of the country, on as uniform a plan as may be found practicable; and the making of such catalogues accessible to all students. (3.) The removal of all fiscal obstructions to the production of English books, and to the importation of foreign books, whatever the apparent magnitude, the supposed incidence, or the plausible pretexts of such obstructions. (4.) Such measures, with respect to the circulation and diffusion of all books, maps, state-papers, and public documents of every kind, which are printed at the national expense, as shall both ensure their presence in all libraries where they are likely to be of public utility, and transform what has too often been a matter of petty intrigues and miserable jealousies into a potent means for the encouragement of science and litera-

Concluding remarks. (5.) Thorough inquiry into the existence, the condition, and the means of vivifying such old libraries, founded for public use, as may have fallen into more or less of desuetude or neglect. And, (6.) Such further amendment of the "Public Libraries Acts" as the results of practical experience may commend to legislative consideration, with a view to their increased efficiency, where action under them shall already have taken place; to their greater adaptability to the varying circumstances of different localities; and to the removal of obstacles which may have impeded their extended adoption.

The measures here roughly suggested, will need time, patience, and industry for their thorough elaboration. One means of setting to work in this direction is close at hand; underlies to some extent every measure which has been indicated; and enwraps within itself an amount of latent power, the full force of which is incalculable. That means

is PUBLICITY. If every library in the country, on which the public has any fair claim, could be brought under public view by a clear and regularly recurring statement of (1.) what it *is*; (2.) what it *has*; and (3.) what it *does*; a long train of improvements would come into quiet and irreversible operation. But this is an instrument which, if it is to produce national results, must be nationally handled. It is *not* a matter for any private society or institution, howsoever patronized. If it were taken up (for example) even by a society, as useful in its proper sphere as has been the "Society for the Encouragement of Arts, Manufactures, and Commerce," it will assuredly fail. If it be taken up, on the other hand, by a public department, such as the "Committee of Council for Education," or, still better, by an individual Minister, possessing due authority and definite responsibility, it will as inevitably tend to make the libraries of Britain, in course of time, the foremost in the world. (E. E.)

Liburni
||
License.

LIBURNI, an ancient people, conjectured by Niebuhr to be of Pelasgic race, who inhabited the northern portion of Illyricum, in the neighbourhood of the Sinus Flanaticus. The country of Liburnia proper was bounded on the one side by the Titius, and on the other by the Arsia; but these limits were only assigned to it after the Gallic invasion, and by no means represent the real strength of the Liburnian people. From a very remote period they had been distinguished as daring seamen, and had spread extensively along the shores of the Adriatic. Corcyra, Issa, and other islands in the neighbourhood, were held by them at the time when the Greeks became masters of these places. The Vindelici and Veneti are believed to have been of Liburnian origin, and the city of Truentum, on the E. coast of Italy, was a Liburnian town. It remained true to the traditions and nationality of the race amid all the fluctuations of the surrounding population. Like all their neighbours, the Liburnians were noted pirates, and their privateers, with a large lateen sail, were for centuries the terror of the seas. Their style of naval architecture was adopted by the Romans in the second Macedonian war. It was chiefly by means of their light galleys that Augustus gained the battle of Actium. The only towns of any importance in Liburnia were Jadera, the capital, and Scardona, at which a famous congress of fourteen Liburnian towns was held. When the country was incorporated with the province of Dalmatia, Jadera was made a colony by the Romans.

LIBYA. See **AFRICA**.

LICENSE, of *Excise*, is a legal document granting permission to deal in certain specified articles of trade. A license is granted annually on application and on payment of the duty, except in cases where an abuse of privilege has been proven. Public-house licenses were granted in England as early as Edward VI. (1551); since which period this mode of imposing duty on excisable articles has been carried into several departments of trade. The annual revenue from licenses now exceeds L.1,000,000.

The following (from *The Business Man's Note-Book* for 1857) is a list of the trades which cannot be carried on in Great Britain without a license, specifying also the rate of license per annum:—

Auctioneers	L.10	0	0

LICHFIELD, an episcopal city, a county in itself, and a municipal and parliamentary borough of England, Staffordshire, is situate in a fertile valley, 119 miles N.W. from London. Extensive breweries and carpet manufactories afford employment to the majority of the population. The city has a free grammar school, said to have been founded by Edward VI.; several national schools; hospitals, &c. The other public buildings are a guildhall, a jail, a theatre, a market-house, a house of correction, the churches of St Mary, St Chad, St Michael, and the cathedral, a most noble structure, partly of early English, and partly of later architecture, and surmounted by three beautiful spires. Lichfield returns two members to parliament, and is governed by a mayor, six aldermen, and eighteen councillors. To Dr Samuel Johnson, who was a native of the town, a monument has been erected in the cathedral. The monument of two children is one of the fines of Sir F. Chantrey's works. Pop. (1851) 7012. See Harwood's *Lichfield*.

LICHTENBERG, GEORGE CHRISTOPHER, the famous illustrator of Hogarth, and caricaturist of Lavater, was born in 1742 at Ober-Ramstadt, near Darmstadt, where his father was pastor. He studied at Darmstadt and Göttingen, at which latter university he was appointed to a professorship in 1770. He was raised to the chair of experimental philosophy in 1777. Previously to this he had twice visited Great Britain, and made himself thoroughly master of English literature. In his declining years he was subject to fits of depression and hypochondria, which severed him almost entirely from the world. He died in 1799. His works were collected by F. G. Kries, in 9 vols., Gött. 1800–1806; and his *Erklärung der Hogarth'schen Kupferstiche*, which remained unfinished at his death, was published in 1794–99.

LICHTENBERG, a principality of Germany, in the S. of Rhenish Prussia, and on the confines of Rhenish Bavaria. Area 232 square miles. The surface is mountainous and well wooded. It was ceded to Prussia by the Duke of Saxe-Coburg-Gotha, in 1834, for an annual rent of 80,000 dollars (L.11,583), and it now forms part of the government of Treves. The capital was St Wendel. Pop. about 38,000.

LICINIUS STOLO. See ROMAN HISTORY, § 2.

LICTORS. See FASCES.

LIECHTENSTEIN, a small independent state of Southern Germany, bounded on the W. and S. by Switzerland, and E. and N. by Tyrol. Area 53 square miles. The inhabitants are chiefly engaged in agriculture and cattle rearing. Some wine is produced. This is the smallest of the states forming the German Confederation, to which it furnishes a contingent of sixty-four men. It has one vote in the full council, and, with several of the other small states, occupies the fifteenth place in the diet. The Prince of Liechtenstein has also extensive possessions in Austria, among which are the dependent principalities of Troppau and Jägerndorf, and which have altogether an area of 2212 square miles, and a population of 600,000. His income from these possessions amounts to at least 1,500,000 florins annually, while the revenue of Liechtenstein itself is only about 22,000 florins. Pop. (1853) 7000. Vadutz or Liechtenstein, the capital, has only about 10,000 inhabitants.

LIÈGE, an important province of Belgium, is bounded on the N. by Limburg, E. by Rhenish Prussia, N.W. by South Brabant, S.W. by Namur, and S. by Luxemburg. Area 1115 square miles. Its surface is level in the N. and N.W., but in the S. and E. parts it is mountainous, and covered by extensive woods, including a portion of the forest of Ardennes. The Meuse, the principal river in the province, flows from S.W. to N.E., through a long and fertile plain, and is joined near the city of Liège by the Ourthe, previously augmented by its tributaries, the Ambleve and the Vesdre. Liège contains several mineral springs, the most celebrated of which are those of Spa. The hot spring of Chaudfontaine is on an island of the Vesdre, about 5 miles from the city of Liège. Its water, which is pumped up by means of a wheel turned by the river, supplies a large bathing establishment, much frequented by visitors. The climate in the N. parts of the province, although damp, is in general healthy. In the S. parts the air is keener and the winter longer. The soil in general is fertile and well cultivated, especially in that long sweep of level land traversed by the Meuse, where hops, corn, and wine are produced in abundance. Large numbers of sheep and cattle feed on its pastures. The chief minerals found in Liège are calamine, lead, alum, and iron ores. The coal mines, however, are the great source of industry and wealth, and in 1850 amounted, in this province alone, to 116. The articles manufactured are chiefly woollens, hardware, iron, and especially fire-arms; and all these, together with cheese, Spa-water, timber, coal, and minerals, constitute the exports of the province. The principal seats of the woollen manufacture are Herve and Verviers; those of the iron manufacture are Herstal, Seraing, and Liège. Glous is celebrated for its straw hats. For the purposes of government, Liège is divided into three arrondissements,—Liège, Huy, and Verviers, and subdivided into twenty-one cantons. Previous to 1789, this province was governed by the Bishop of Liege, who was a prince of the empire. It was afterwards subject to the French till the fall of Bonaparte, when it was incorporated into the kingdom of the Netherlands. In 1830 it became a part of the kingdom of Belgium. Pop. (1854) 494,793. See BELGIUM.

LIÈGE (Dutch *Luyk*, Ger. *Lüttich*), an important manufacturing town of Belgium, capital of the province of Liège, situate near the confluence of the Ourthe and the Meuse, in N. lat. 50. 39. 22., E. Long. 5. 31. 42.; 54 miles E. by S. from Brussels. Though in a fine situation, the city is by no means beautiful and healthy, owing to the smoke of its numerous manufactories, the narrowness of many of its streets, and the height of many of its houses. It is divided into two portions, the upper and the lower town: the former on the declivity, and the latter at the foot of a hill. The River Meuse, on entering the town, divides into several branches, which are lined by quays, and crossed by numerous bridges. Liège is famous for its manufacture of iron; and the fire-arms, cannons, and machinery it produces, are said to surpass in quality those of all other countries except Great Britain. The number of cannons and fire-arms submitted to the Board of Approval, in 1849, were 405,030; and in 1850, 432,347. There are large factories at several of the suburbs, especially at Seraing, where spinning machinery and steam-engines are extensively produced. The other manufactories of Liège are,—hardware of all kinds, woollen and cotton fabrics, hats, glue, tobacco, glass, leather, and other articles. There are likewise steel-works, breweries, distilleries, tanneries, and dyeing-houses. The city has a considerable trade, which is greatly facilitated by the roads, railways, and canals, that traverse the country in all directions. The great cause, however, of its prosperity are the coal-mines that abound in the neighbourhood, and are extended even under the town and the River Meuse. Besides coal and iron, the district produces also zinc, lead,

Liegnitz
||
Life-Pre-
servers.

copper, sulphur, alum, marble, and slate. Liège was once fortified, but its sole defence now is a citadel erected at the N. side of the city, on St Walburg's Mount. Its churches are numerous, of which the following are the principal:—The cathedral, founded in the thirteenth century; the church of St Jacques, the finest of all the sacred edifices; and the churches of St Denis, St Bartholomew, St Croix, and St Martin. The university, erected by the King of Holland in 1817, comprises the faculties of law, theology, and medicine; and possesses a museum, containing, among many other specimens, a collection of fossils chiefly culled in the neighbourhood. Besides the Palais de Justice, which is a splendid specimen of ancient architecture, the other public buildings are, a theatre, an episcopal seminary, a royal college, several schools, a library, containing, in addition to numerous volumes, many curious manuscripts, an academy of fine arts, and other educational and benevolent institutions. Liège is the see of a bishop, and the seat of a superior court of justice. In the tenth century, the Emperors of Germany elevated the Bishops of Liège to the rank of independent princes. In 1467, the citizens, rebelling against their liege lord, Charles the Bold, were compelled by him to raze a great part of their fortifications. Pop. (1851) 81,789.

LIEGNITZ, one of the three governments into which Prussian Silesia is divided, comprising the N.W. part of Upper Silesia, and that part of Upper Lausatia which now forms part of Prussia. It is bounded on the N., N.E., and N.W. by the provinces of Posen and Brandenburg, S.E. by the government of Breslau, and S.W. by Bohemia. Area 53,000 square miles. The surface is rugged and mountainous in the S., and traversed by ridges of the Riesengebirge, several of which exceed 4000 feet in height. It then slopes rapidly northward to the great plain of the Oder, which flows from S.E. to N.W. through the government, and forms part of its northern boundary. Besides the Oder, the chief rivers are its affluents, the Katzbach, Bober, and Neisse. The soil is generally sandy, and the corn produced is not sufficient for the wants of the inhabitants. Large numbers of sheep and cattle are reared. Pop. (1849) 921,002.

servers.

LIEGNITZ, the capital of the above government, is situated at the confluence of the Schwarzwasser and Kartzbach, on the Berlin and Breslau Railway, 40 miles W.N.W. of the latter town. It was formerly a place of some strength, but its ramparts are now laid out in public gardens, and only its four gates remain entire. The town, though old, is handsomely built and pleasantly situated. Its old castle has been mostly rebuilt since a fire, which destroyed a great part of it in 1834. In the *Fürsten Capelle* are monuments of the princes of the line of Piast, a family which, from 775 to 1675, when it became extinct, gave twenty-four kings to Poland, and 123 dukes to Liegnitz. This town is the seat of superior, judicial, and other courts for the government; and has a gymnasium, a *Ritter* academy for the education of the sons of Silesian noblemen, an orphan asylum, two hospitals, workhouse, and theatre. The chief manufactures are woollen, linen, and cotton stuffs, starch, beer, and tobacco. There are numerous gardens in the vicinity, and the gardeners are reported to be the most skilful of any in Silesia. Here, on 16th August 1760, Frederick the Great totally defeated the Austrians. Pop., including military (1849), 14,934.

LIERRE, or LIER, a town of Belgium, province of Antwerp, at the confluence of the Great and Little Nethe, 10 miles E.S.E. of Antwerp. It is generally well and regularly built, and has a large and elegant church, hospital, prison, barracks, orphan asylum, and several almshouses. The Nethe is navigable up to the town, and affords it the means of carrying on a considerable trade in its various manufactures. These comprise cotton, woollen, and silk fabrics, lace, soap, leather, cutlery, beer, brandy, tobacco, &c. Pop. (1851) 14,069.

LIEUTENANT (*locum tenens*, holding the place of), in a military sense, means the person second in command: as, lord-lieutenant, one who represents the prince or governing power; lieutenant-general, one who stands next to the general; lieutenant-colonel, the next to a colonel; and lieutenant, the next to a captain, in every company of both foot and horse, and who takes the command upon the death or absence of a superior officer. See ARMY, COMMISSION, &c.

LIFE-GUARDS. See GUARDS.

L I F E - P R E S E R V E R S .

ALTHOUGH it too frequently happens that an accident which materially endangers the life of an individual, deprives him, in the meantime, of that presence of mind which alone would enable him to take proper measures for his safety; yet to have meditated, in an interval of leisure, upon the best method of proceeding in case of emergency, must tend greatly to diminish the embarrassment and confusion that commonly accompany the accident, even if it should not be thought necessary to provide any particular apparatus for the purpose of escaping the danger. There are also many ways in which those who are not immediately involved in the disaster may contribute to the preservation of life, whether actuated by interest, or by humanity only; and the modes of relief will therefore be naturally divided into the *internal* and the *external*, whether relating to *fires* or to *shipwrecks*.

Internal Fire-Escapes.—Whenever a family establishes itself in a residence not detached from others, it becomes of importance to ascertain what facilities the house affords for ascending to the roof, and for passing to those of the neighbouring houses. It is scarcely possible that a conflagration should extend at once to the contiguous houses on each side, before the inhabitants of the house in question

have had time to escape. But in a detached house, if there are not two or more staircases remote from each other, and even in a house contiguous to others, when there is no facility of communicating by the roof, it becomes highly expedient to provide some *internal means* of escaping through the windows in case of fire, and to have on every floor a strong rope, with a hook or a loop at the end, by which it may be fastened to a bed-post, so as to enable an active person to descend by its help out of the window, finding from time to time a partial footing in the inequalities of the wall. This process will be greatly facilitated by having the rope knotted at intervals of about a foot throughout its length; the knots being nearly as convenient as the blocks or clips that are sometimes made for the purpose of retarding the descent, by holding them, and regulating the friction by the pressure of the hand;¹ unless the clip be attached to a strong cross bar, on which a person may sit, while he regulates the position of the clip by its handles, and allows himself to descend with more or less velocity at pleasure. The arrangement for this purpose may be made by a roller, or pipe, sliding on the rope, and pushed down so as to open the handles of the clip and tighten its teeth

¹ Emerson's *Mechanics*, figs. 228, 229; Leupold's *Theatrum Machinarum*, plate liv.

Life-Pre-
servers.

when the person holds by the roller and draws it down (fig. 1); and, on the contrary, the clip may be opened by pressing on the handles with the other hand, or with the thighs; or any other simple mode of regulating the clip may be adopted, provided that it be not liable to be misunderstood, or misapplied, in a moment of confusion. After all, a rope-ladder would perhaps be preferable, as not being liable to be deranged; it is often kept ready made in the shops; and, in the absence of any other rope, a common bed-cord will generally be found strong enough to support the weight even of a stout man; for a quarter-inch rope may be safely trusted with 2 cwt., and ought indeed to support three times as much, if new and of good quality.

Fig. 1.

In speaking of the duty of providing internal means of escape, Mr Baddeley remarks,¹ that "egress can sometimes be made at the top of a house, either by a door or by an opening made in the roof with a poker for the purpose. Sheets and blankets tied together and fastened to the bed-post, or the bed-cords attached in the same way, afford the means of descending; the feather-bed, &c., thrown out serve to break the fall when jumping from the window as the last alternative. With a little contrivance, women and children may be lowered by means of the bed-clothes. Upon these occasions, all depends upon the persons in danger retaining so much presence of mind as will enable them to avail themselves of the best means in their power; and it often happens that pressing danger develops a great deal more ingenuity and intrepidity in individuals than they have previously taken credit for."

External means of escape from fire.—The external means to be employed in cases of conflagration must be provided by the managers of fire-offices, or by other public officers; and every ingenious workman whom they may employ will be able, at his leisure, to devise such apparatus as he can the most conveniently execute, and to give it a full trial in the absence of all danger; it will therefore only be advisable that he should compare for himself the particular inventions which have been suggested for this purpose, and that he should choose from among them such as he thinks most likely to do him credit; and he may, indeed, very possibly find means of improving on any of them.

In Leupold's *Theatrum Machinarum* (plates liv. lv.), we find the representation of a chair calculated to be drawn up or down by means of pulleys. Mr Varcourt obtained, in 1761, the approbation of the Parisian Academy of Sciences for his invention of a hollow mast, fixed in a waggon, and supporting a stage, with the means of ascending and descending. (*Hist.* p. 158.) In the beginning of the present century, a fire-escape of Mr Audibert was approved by the Parisian Institute. (*Mém. Inst.* iv.) A committee was also appointed for examining several similar inventions at the Lyceum of Arts, and a medal was awarded by it to Mr Dajon, for his apparatus, which consists of a platform carried on wheels, supported by three frames, with brass wires, on which boxes are made to slide up and down for the conveyance of persons or of furniture. (*Annales des Arts. Répertoire* ii., vol. i., p. 439.) Mr Collin's invention of pipes raised by ropes, and affording a centre to a long lever, is described in the fourth volume of the *American Transactions*, and in the *Repertoire* (vol. xv., p. 35). In the thirty-first volume of the *Transactions of the Society of Arts* for 1813 (p. 244), we have an account of a fire-escape

invented by Mr Adam Young, for which he received a Life-Pre-medal from the society. It appears to constitute by far the most portable of ladders, consisting of cross bars or rounds connected by ropes, and having their ends fitted together, so as to form a pole, which is readily elevated to the window; and the rounds being separated, and the hooks at the end properly fixed to the window-frame, the whole forms itself into a very convenient ladder of a mixed structure. The thirty-fourth volume, for 1816 (p. 227), contains a description of Mr Braby's fire-escape, consisting of a car made to slide on a strip of plank fixed to a pole, and governed by a rope, which is cased with iron, to protect it, in case of necessity, from the effect of the fire.

The fire-escape in use in the metropolis is founded on the invention of Mr John Davies, submitted to the Society of Arts in 1809. It consists of three ladders connected to, and sliding upon, each other by means of ropes worked by a small windlass; a second windlass raises and lowers a cradle, which is supported by ropes passing over pulleys at the top of the uppermost ladder. This machine is mounted upon a low four-wheeled truck, and can be drawn by a horse, or by six men. As improved by Mr Gregory, the three ladders sliding on each other, when lowered, are balanced horizontally on a frame, mounted on a light four-wheeled carriage, so as to be run under low gateways, &c. The ladders being brought into a nearly vertical position, are raised by a small windlass in front of the machine to any height between 10 and 40 feet; when the ladders are inclined towards the window, and the top one made to rest against the sill. A greater elevation than 40 feet may be obtained by means of joints fixed at the top, and a cradle is also used for those who are too timid to descend ladders.

A great many other forms of fire-escape might be noticed, for it is one of those subjects which readily appeal to the ingenious mechanic in a large city where fires are numerous; and every form of fire-escape must at times fail. Hence there has been a sort of competition among uneducated inventors, who have displayed some mechanical ingenuity, but have not, as far as we are aware, developed any new principle.

The modes of extinguishing fires are not precisely the object of the present inquiry. The engines employed for the purpose are described under *HYDRODYNAMICS*. Within the last few years, an apparatus called a *fire-annihilator* has attracted some attention; its object is to generate a large amount of gaseous matter, which will not support combustion, and which being injected into the burning mass, is to extinguish the fire by displacing the air. The non-supporting gases are generated by means of chlorate of potash and sugar contained in a perforated cylinder, and ignited, when required, by crushing a small glass vessel containing sulphuric acid. There is also a contrivance for saturating the gases with moisture.

Many attempts have been made to prevent fires by rendering houses fire-proof, either by coating the timber with some unflammable substance, or by rejecting combustible substances altogether in building. The Earl of Stanhope's method of fire-proofing consisted in the use of non-combustible materials, with, among, and between the timbers forming the frame-work of a house. Many other methods have been proposed for coating the timbers with plaster, covering the houses with fire-proof paint, soluble glass, &c. We do not attach much importance to these inventions, for if the house contain goods and furniture of an inflammable kind, and the fire once obtain an ascendancy over them, the house will scarcely escape destruction. In the construction of floors and roofs, Messrs Fox and Barrett propose to substitute for timber joists of iron, and successive layers of incombustible materials, such as mortar, concrete, &c., the floors being finished with a smooth and uniform

Life-Pre-
servers.

¹ Hebert's *Engineers' and Mechanics Encyclopædia*.

Life-Pre-
servers.

surface of lime and sand well trowelled up to a face, and coated with linseed oil; while the roofs are finished with a coating of coal-tar, paper, and sand, instead of the ordinary timber and slate. Mr Frost proposes for the floors of rooms to use hollow earthenware tubes, embedded in cement, and so combined as to cover the whole floor. Mr Loudon recommends that the floors be formed of flat tiles and cement. Mr Payne proposes to render timber fire-proof by means of a solution of sulphuret of barium or of calcium, forced into the timber by appropriate apparatus, and then adding an acid or a solution of some substance, such as sulphate of iron, which unites with the barium or calcium, and sets free the sulphur. Iron joists and girders have been largely used in the construction of fire-proof buildings; but it has been shown by Mr Braidwood, that a fire originating in the goods stored in these so-called fire-proof warehouses sometimes produces a temperature nearly equal to the melting point of cast-iron; while the jets of water from the fire-engines crack and bring down beams and columns of cast-iron which are used in supporting the upper floors, so as really to cause a greater destruction of life and property than timber beams, which resist the fire for a considerable time, and permit the inmates to escape, and the firemen to penetrate the building with their branches and water-hose, which they are sometimes forbidden to do if the building is known to have iron-girders. A better plan for fire-proof buildings seems to be the use of groined brick arches, supported by pillars of brick laid in cement.

Internal Means of Escape from Shipwreck.—The means of escaping from shipwreck may be similarly divided into *internal* and *external*, or into the precautions to be taken by the ship's company, and the measures to be adopted by persons on shore. The internal means depend either on enabling the individuals to swim or float, or establishing a connection with the shore by ropes; and of the former, we may first consider those which require no particular preparation before the occurrence of the accident that calls them into action, and which are, therefore, the most universally applicable.

Of such expedients, the most effectual appear to be those which depend on the employment of empty water-casks for assisting the ship's company to drift on shore. 1. A paper on the arrangement of water-casks, to serve as floats in case of shipwreck, appears in the publications of the Society for the Improvement of Naval Architecture, dated in 1796 (vol. ii., p. 51). 2. In 1818, Mr Grant of Bideford obtained a gold medal from the Society of Arts, for the invention of a life-preserver, consisting of a thirty-six gallon cask, with some iron ballast fixed on a wooden bed, and lashed to the cask, and with ropes round it for the men to hold; and it was found that ten men were supported by it with convenience in tolerably smooth water, the bung of the cask being well secured by cork (vol. xxxvi., p. 63). The ballast could be of very little use, and a cask simply tied round with a rope, like a common parcel, would probably answer the purpose equally well. It would, indeed, be prudent for every ship in a storm, on a lee shore, to have a few of her casks well emptied and stopped, and tied in this manner, before the actual occurrence of imminent danger. 3. In the thirty-seventh volume of the *Transactions of the Society* (p. 110), there is an account of Mr Cook's life-raft, consisting of a square frame with canvas nailed across it, supported by a cask at each corner, for which the gold medal was voted to him. 4. It is followed by a description of Lieutenant Rodger's life-raft (p. 112), which obtained a similar compliment. This raft has the advantage of requiring only such materials as are usually found on board of every ship; capstan-bars, boat-masts, yards, or any other spars of moderate dimensions, which are tied together so as to make a sort of waggon frame, with a large cask fixed on each side; it appears to

afford a very convenient support to the men, but it can scarcely possess any great strength for resisting the force of the breakers.

Mr J. Bremner, a clergyman in the Orkneys, had received a medal from the Society in 1810, for his method of converting any ship's boat into a life-boat by putting into it three or four casks lashed to the keel, which is to have ring-bolts fixed in it for receiving the ropes by which the casks are fastened; he gives particular directions for making all the necessary arrangements, in the twenty-eighth volume of the *Transactions* (p. 134); he particularly advises that no use should be made of the natural buoyancy of the cavity of the boat, but that the bottom should be perforated without hesitation, wherever the hole would afford any additional facility for fixing a rope. Captain Manby's jolly-boat, fitted as a life-boat, "at the expense of three pounds," seems to be comprehended among those preparations which are to be made previously to the voyage.

The buckling a soldier's canteen on his breast as an assistance to enable him to float, belongs to those temporary expedients which may occasionally be employed with advantage. Tying a hat in a pocket-handkerchief, and holding it as a float, has been recommended by Mr Lawson in the *Philosophical Magazine* (vol. xx., p. 362); he advises that the crown of the hat should be held downwards, and observes that a stick may be employed, to enable us to use two or four hats at once; but this method can only be adopted when the accident occurs in very still water.

The first and most obvious preparation for enabling a person to float, is the learning to swim. It is well known that swimming is scarcely ever sufficient to enable a seaman to reach the land from a ship that has been wrecked, without some assistance; and many have certainly been drowned from depending too much on their own strength; but for a momentary support, and to afford courage and presence of mind to seek for other aid, there is no question but that the faculty of swimming possesses an inestimable advantage. A boy generally learns to swim by the help of his schoolfellows better than by any general rules, and more agreeably than in a school of natation; but it may be of some use to observe, that the act of diving to the bottom and re-ascending, in tolerably shallow water, is much more easily performed by a beginner than that of simply supporting himself on the surface; and when he has thus acquired the feeling of the immediate effect of his arms in propelling and sustaining him, he soon finds out the means of employing his feet in their assistance. The art of swimming has, however, been systematically treated by Bachstrom, *Kunst zu Schwimmen*; 8vo, Berlin, 1742; by Thévenot, *Art de Nager*, Paris 1711, and by Bernardi, *Arte Ragionata del Nuoto*, 2 vols. 4to. Naples, 1794.

It is easy to convince ourselves, by trials in a warm bath, without reference to Robertson's experiments (*Phil. Trans.* 1757), that a substance possessing a very small degree of buoyancy is sufficient to enable the human body to float without effort. In fact, when the chest is fully expanded, the thinnest and most bony person will commonly float in sea-water; but the effort of keeping the chest expanded is as fatiguing as any other muscular exertion; and when the chest collapses, the fattest people may be in danger of sinking, unless they have learned to swim. Sir William Hamilton, indeed, tells us that, in 1783, "a woman of Scilla, four months gone with child, was swept into the sea by the wave" accompanying the earthquake, "and was taken up alive, floating on her back at some distance, nine hours after; she had been used to swim; her anxiety and suffering, however, had arrived at so great a pitch, that just at the time that the boat which took her up appeared, she was trying to force her head under water, to put a period to her miserable existence."

Life-Pre-
servers.

Life-Pre-
servers.

In China, a frame of bamboo surrounding the person is used for a float, and the lightness and strength of this substance must well adapt it for the purpose; sometimes also a gourd is tied to a child, to secure its floating in case of accident. The inflated goat-skins used from time immemorial by the Arabs, or the seal-skins employed by the Chilians, have the disadvantage of being easily rent or torn by a rock or a spar; an objection which is also more or less applicable to all substances containing air; for example, to the air-jackets described in Leupold's *Theatrum Pontificum*, published about 1724. A float of a semicircular form was recommended by Ozanam, the author of the *Recreations*; and Bachstrom, in his *Art of Swimming*, proposed to float a troop of cavalry, by fixing cork to the saddles. The cork jacket of Gelacy is described in the *History of the Parisian Academy of Sciences* for 1757, and Lachapelle's *Scaphander*, which is considered an improvement on it, in the volume for 1765. In the year 1764 the attention of the British public was particularly called to the floating powers of cork, by some experiments which were made with cork jackets on the Thames, together with some comparative experiments on air-jackets; and Dr Wilkinson, in the *Philosophical Transactions* for 1765, describes some experiments by which he ascertained that about a pound of cork was amply sufficient to enable a man of ordinary size and make to float without effort. It is almost superfluous to enumerate the multitude of trifling variations that have been made in the arrangements of cork jackets and air-jackets, apparently for the purpose of exciting a momentary interest, though possibly from the best motives. Mr Bosquet advised a bag of cork shavings to be kept in readiness by each person; the *Seaman's Friend* was composed of two pieces of cork, united by straps; the *Collinetta* was a hollow vessel of copper, divided into cells; a "marine spencer" has been described by Mr Spencer, in the sixteenth volume of the *Philosophical Magazine*, consisting only of a number of old corks, arranged so as to form a girdle; and in 1806, Mr T. C. Daniel obtained a gold medal from the Society of Arts, for the invention of an apparatus of waterproof leather, surrounding the body, which, according to the testimonials he produced, had saved the lives of some persons who had been sailing in a pleasure-boat on a river. In smooth water, it has been suggested that throwing a foot-ball, with a small weight tied to it, to the person immersed, would often afford sufficient assistance; and, with respect to floating, there is no doubt that any of the assistances which have been proposed would be sufficient if they were at hand: but there is another object, to which it is necessary to attend, in cold, and even in temperate climates, that of supporting a temperature compatible with life and health, if the immersion is likely to be of long duration; and an additional provision of worsted stockings, jackets, and trowsers, will be almost as essential, in such cases, as the means of obtaining buoyancy.

The invention of India-rubber cloth led to the introduction of inflated belts, the advantages of which, compared with cork, and other forms of belt, are their greater buoyancy compared with their bulk, and their greater portability, for, when emptied of air, they can be folded up, and packed into a small space. The objections to them are their liability to get punctured or torn, and to decay, from being put away damp; the metal valves by which they are inflated may also get out of order; during the hurry and confusion of a wreck they are liable to be only partially inflated, and the valves to be only half screwed up, so as to allow of the escape of the inclosed air.

Commander J. R. Ward, R.N., inspector of life-boats to the National Life-Boat Institution, has invented a belt with four compartments, which admit of being separately inflated, thus mitigating the danger arising from puncture or injury to the inflating valves; it has a buoyancy equal to

30 lb., and should two of its compartments be disabled, the remaining two would be sufficient to float the wearer.

Life-Pre-
servers.

For the rough purposes of ordinary boat-work, Commander Ward insists on the advantages of cork as a material for life-belts, and he has invented a form of belt, which has been selected by the National Life-Boat Institution for the use of its life-boats' crews. The buoyant power of each belt is from 20 to 24 lb.; the cork is uncovered, so that its quality can be seen, and it is divided into numerous narrow pieces, each of which is sewed separately to a strong linen or duck belt, which covers the body from the arm-pits to below the hips. The pieces of cork are distributed in two rows, one above, the other below the waist, and the belt is secured closely about the body by means of strings passed round the waist, between the two rows of cork. It is further secured by other strings, crossed over the shoulders. By this arrangement the trunk of the body is enveloped in cork, attached so as to be quite flexible, and to allow of the usual movements of the body without inconvenience, while it protects the body against injury from blows, and is a warm covering in cold weather.

Various forms of buoyant mattress have been contrived by Mr Laurie and others. As manufactured by Mr Silver, numerous waterproof tubes are partly distended with horse-hair, woollen flocks, or cocoa-nut fibres, so that, should one or more of the tubes fail, the others may suffice to sustain the required weight on the water. The tubes are made up into mattresses, pillows, and floats,—the last to be placed under the thwarts of boats. A mattress weighing 17 lb. sustains in the water 284 lb. A pillow sustains 28 lb. A mattress for emigrant vessels, sold at 9s., was proved at the Great Exhibition. It sustained 96 lb. in the water during five days, without being injured. Floating mattresses are also made, filled with cork shavings. In the Great Exhibition, Mr Rhind had various models of deck seats and benches for steamers, so constructed as to be readily formed into rafts, each of which was capable of sustaining eight persons.

For the second object which is desirable to a ship in distress, that of obtaining a safe communication with the shore, it has been usual of late years to rely principally on the humane exertions of persons who may be on the coast, and who may have made preparations for this purpose; and with this view, some instructions for properly co-operating in the measures to be adopted with Captain Manby's apparatus have been liberally distributed to all ships when they received their papers from some of the British custom-houses. There are, however, some simple expedients which may be adopted for this purpose by persons on board of the ship; for example, the making a kite with a pocket-handkerchief stretched over a hoop, and causing it to carry a cord to the lee shore, by means of which a stronger line, and at last a hawser, may be drawn by persons standing on the beach. A line may also sometimes be carried on shore by a cask, allowed to drift before the wind; and a bag has been recommended to be attached to such a cask, or to a buoy, in order to act as a sail, and to insure its crossing the surf. Mr Cleghorn was also rewarded, in 1814, by the Society of Arts, for the invention of a buoyant line, having a heart of cork, to obviate the inconvenience which would arise from its sinking and being dragged on the stones under the breakers; but he observes, that in heavy storms there is generally a current along shore which renders the method almost impracticable. (*Transactions*, xxxii., p. 181.) A Mr Wheatley assures us, in Captain Manby's *Essay*, that his own life, and that of eight other persons, was saved, in 1791, by a lead line, which was carried on shore by a Newfoundland dog that he happened to have on board, when two good swimmers had been drowned in the attempt to swim on shore. It had occurred to Lieutenant Bell, in 1791, that a rope might be thrown from a ship which had

Life-Pre-
servers.

struck, by means of a mortar carrying a heavy shot, and upon the principle of the gun harpoon; and he showed the practicability of the suggestion by an actual experiment, in which a deep-sea line was carried to a distance of about 400 yards. (*Trans. Soc. Arts*, xxv, p. 136.) He recommended that every ship should be provided with a mortar capable of carrying such a shot, and observed that it might be placed on a coil of rope to be fired, instead of a carriage. The line was to be coiled on handspikes, which were to be drawn out before the mortar was fired. In 1792 he received a premium of fifty guineas from the Society of Arts (*Transactions*, x, p. 204); and he obtained his promotion in the Ordnance as an acknowledgment of his merits. The shot was to weigh about 60 lb. or more, and the mortar 5 or 6 cwt. The experiments of the French artillery at Laferre were subsequent to those of Mr Bell, though they have sometimes been quoted as the first of the kind.

It has, however, generally been thought impracticable to manage a mortar with effect under the circumstances of actual shipwreck; and Mr Trengrouse has preferred a rocket, as more easily fired, and as having a smaller initial velocity than a shot, so that the rope would be less in danger of being broken by the impulse. He found that a rocket of 8 oz. carried a mackerel line 180 yards, and a 1 lb. rocket 212; and, in some experiments made under the inspection of the Society of Arts, a rocket $1\frac{1}{4}$ inch in diameter carried a cord across the Serpentine River in Hyde Park. The musket is provided with a valve, to prevent the escape of the materials of the rocket, and it is to be fired with a little powder, without wadding. The whole apparatus is packed in a chest, containing from eight to twelve rockets, the musket, a life-spencer, a chair to traverse on a rope, a canvas bag, and a ball of wood to throw to a person swimming. Mr Trengrouse was complimented with a medal from the Society of Arts in 1820. (*Vol. xxxviii*, p. 161.)

External Means of Escape from Shipwreck.—The means to be employed by persons on shore, in cases of shipwreck, depend either on projecting a line over the ship, or on the use of a life-boat. Mr Bell had cursorily observed that a line might be carried over a ship from the shore by means of his mortar; but for the actual execution of this proposal, in a variety of cases, we are indebted to the meritorious exertions of Captain G. W. Manby, whose apparatus, according to the report of a committee of the House of Commons, dated in March 1810, appears "to be admirably adapted to its purpose, and to have been attended with the fullest success in almost every instance." In consequence of this report, Captain Manby was thought worthy of a parliamentary reward; and he afterwards published a description of his inventions, under the title of *An Essay on the Preservation of Shipwrecked Persons*, 8vo, London 1812. He had previously received a gold medal from the Society of Arts in 1808 (*Transactions*, xxvi, p. 209). His success makes it expedient to extract from his *Essay* a detailed description of the apparatus, and it will be easy to make it somewhat more intelligible by a slight alteration of the order of arrangement.

"The method of affixing a rope to a shot, for the purpose of effecting communication, when projected from a piece of ordnance over a stranded vessel, was at length succeeded in, by introducing a jagged piece of iron, with an eye at the top, into a shell, and securing it by filling the hollow sphere with boiling lead; and in another way, by drilling a hole through a solid ball, and passing a piece of iron, with an eye to it, as before described, to the bottom, where it should be well secured by riveting.

"To produce the means of connecting a rope to a shot, and prevent its being burnt, and rendering it 'irresistible' to the powerful inflammation of gunpowder, was the labour of infinite time, and the number of experiments to accom-

plish it is beyond all possible conception. Chains in every variety of form and great strength breaking, proved that it required not only an elastic, but a closer connected body. At length, some stout platted hide (fig. 2), woven extremely close to the eye of the shot, about 2 feet in length beyond the muzzle of the piece, and with a loop at the end to receive the rope, happily effected it.

"This method is certainly desirable, as the rope may, immediately [as] it is required, be affixed to the loop, and applied in service. The form of the platted hide may

Fig. 2.

likewise be woven by twisting it in the manner that the lashes of whips or ropes are spun; there is another

method, by passing the rope through a case of leather, taking the greatest care that it is so well secured at the eye of the shot, as to leave no room for the slightest play, as is represented by the annexed *barbed shot* (fig. 3).

"When the crews of the distressed vessel are incapable of availing themselves of the benefits arising from communication, they having previously lashed themselves in the rigging to prevent being swept away by the sea, which is repeatedly breaking over them, and when, from long fatigue and the severity of the storm (on which occasions it too frequently occurs), they totally lose the use of their limbs, and are rendered incapable of assisting themselves in the slightest degree—the advantages of this shot are, that, on its being projected over the vessel, and the people of the shore hauling it in, it firmly secures itself on some part of the wreck or rigging, by which a boat can be hauled to the relief of the distressed objects; and by the counterbarbs it is rendered impossible [that it should] give up its hold, or slip, while that part of the wreck remains to which it has secured itself.

"Among the many that have been saved by this shot, the following are testimonials of a few of the cases:—'We, the crew of the brig Nancy of Sunderland, do hereby certify that we were on board the said vessel when she was stranded on the beach of Yarmouth, on Friday morning, the 15th of December 1809, and compelled to secure ourselves in the rigging to prevent being swept away, the sea running so high over the vessel. And we do further declare and certify that Captain Manby, firing a rope with a hooked shot, securely holding on the wreck, enabled a boat to be hauled from the shore over the surf to our relief; otherwise we must inevitably have perished.' This certificate is attested by six signatures.

"Facilitating communication is at all times of importance; but when the stranded vessel is in momentary danger of going to pieces, this point becomes a consideration of extreme urgency. I feel a persuasion that this particular service can only be carried into effect by a small and light piece of ordnance, the range of which is consequently very inconsiderable, when compared with that of a large and heavier piece, as it is weight alone that conveys the rope. In order, therefore, to increase the powers of a shot projected from a small mortar, its natural form must be varied, so as to give it additional 'preponderance.' The annexed shape, in the form of a pear (fig. 4), has been used with the greatest success; for, by the increased weight, the shot's momentum and power over the line is in consequence considerably augmented in its range; and when made to fit the piece as close as possible, a great increase of velocity is likewise produced from that decrease of windage.

Fig. 4.

Life-Pre-
servers.

Life-Pre-
servers.

"Portability in the construction of a piece of ordnance (as just described) is the very essence of this service; and communication with the stranded vessel or wreck may be effected with a cord, by which cord a rope can be conveyed, and by that rope a hawser or cable sent to the distressed vessel; for this purpose the annexed was constructed" (fig. 5).

Fig. 5.

"A person completely equipped with every necessary apparatus to effect communication with a vessel driven on a lee-shore . . . the horseman, fully equipped, travelled a mile and a half, the howitzer was dismounted, and the line projected 153 yards, in six minutes.

"The application of a small piece of ordnance likewise offers particular advantages, capable of being employed from a boat to go to the assistance of a vessel grounded on a bar when running for a harbour, the necessity of which repeatedly occurs, and was twice witnessed at Blakey on the 10th of November 1810, when boats endeavoured to go to their relief, and were enabled to get out of the harbour on the ebb tide, within 20 yards of the vessel; but it was found impossible to approach them nearer. Had such boats been provided with a piece of this description, and the same firmly secured on a stout piece of plank, by the holes left at each corner of the iron bed, they might have projected a small rope, coiled in a crate or basket made to the form of the bow of the boat; and the persons in the boat, so provided, would not have remained the distressed spectators of the untimely end of their fellow-creatures, without being able to afford them the smallest relief, although so little was then wanted for that desirable purpose.

"Although advantages have been pointed out in the use of these small mortars, it is necessary to be kept in remembrance, that they are produced for particular services; as the nature of the coast, and circumstances attending the distressed vessel, will direct what piece is best adapted to the undertaking. To enable the mind to form a judgment of what can be effected by other pieces, the following are the minutes of experiments made with a $5\frac{1}{2}$ -inch brass mortar, stating the quantity of powder used, and distance the ropes were projected against a strong wind, at the angle of 17° (elevation): weight of the mortar and bed about 300 lb. :—

Ounces of Powder.	Yards of inch and half Rope.	Yards of Deep-sea Line.
4	134	148
6	159	182
8	184	215
10	207	249
12	235	290
14	250	310

"With a short 8-inch mortar, the weight of which and bed was supposed to be about 700 lb.; the angles of elevation uncertain :—

Ounces of Powder.	Yards of Deep-sea Line.	Yards of two-inch patent Sunderland Rope, capable of hauling the largest Boat from a beach.

"Directions for using the Apparatus.—When the rope (which should be pliant and well stretched) is brought on the beach or cliff opposite to the stranded vessel, the most even spot, and free from projecting stones, should be se-

lected to lay it on, and great care be taken that no two parts of it whatever overlay or even touch each other, nor must it be laid in longer lengths than of two yards. But to project a small line or cord, it will be necessary, if it is required, to contract the faker to half a yard at most, to avoid the jerk received at the end of each right line. The best method, with such a description of cord, is to lay it on the ground in the most short and irregular windings, to relieve it from this powerful impulse. To prove the effect of the impulse on a rope, if it is faked in lengths of 10 or 15 yards, it will break each time, as it then becomes a most powerful pendulum. These precautions are absolutely necessary to the success of the service.

"The following has, after various trials, been found a certain method of laying the rope, and placing it into compartments." (*French Faking*, fig. 6.)

"A particular attention to this mode will never fail with a good rope, when the impediments are removed that might otherwise obstruct its rapid flight. Its

Fig. 6.

advantages are, that it will allow the eye rapidly (yet correctly, *just before firing*, which is absolutely necessary) to pass over the different compartments, and at once discover if any fake has been displaced by the storm, or by any other casualty or accident come in contact with another part, which would destroy its application by the rope breaking.

"It may likewise be coiled in the manner used in the whale fishery, *whale lair* (fig. 7); and in the method called *chain faking* (fig. 8):—

Fig. 7.

Fig. 8.

"It is, however, necessary to add, that great attention is required in laying it agreeably to the two latter methods, arising not only from the arm being liable to get under certain parts of the rope, and thereby displace it, but from the great anxiety of mind natural on these occasions, where the lives of fellow-creatures are literally dependent on the correctness with which the rope is laid; it is therefore extremely difficult, in a moment of agitation, to determine whether any overlay has taken place, an error that would infallibly destroy every endeavour, and occasion even the fate of those whose lives we might be exerting ourselves to preserve. Could persons in the performance of this service be always collected, the two latter methods would have a decided advantage over the first mode of faking, they being laid in a much less space of time.

"As all these methods of laying the rope occupy time to place it with the care necessary; and as it has repeatedly happened that vessels, very soon after grounding, have gone to pieces, and all hands perished; it was necessary to pro-

Fig. 9.

duce a method of arranging the rope, so that it could be immediately projected as soon as it arrived at the spot; and

Life-Pre-
servers.

Life-Preservers. none proved so effectual as when brought ready in a basket (fig. 9).

"In this case, the rope should be most carefully laid in alternate tiers or fakes, no part of it overlaying, and it should be well secured down, that in travelling it be not displaced; but, above all, no mistake must happen in *placing the basket properly*. For example, that the end of the basket, from which the shot hangs in the above figure, should be previously marked, and must be placed towards the sea or wreck, that the rope be delivered freely, and without any chance of entanglement. It will be scarcely necessary to add, there will be several tiers of the rope when laid. The utmost care and attention are required in laying the rope in tiers with strict regularity, to prevent entanglement."

"The next is the application of the mortar. If the wind is sideways to the shore, it must be pointed sufficiently to windward to allow for the slack of the rope lighting on the object, as the rope will, of course, be considerably borne to leeward by the effect of a strong wind, and by its being laid at a low elevation insures the rope falling against the weathermost part of the rigging. While this service is performing, great care should be taken to keep the mortar dry; nor should it be loaded until everything is ready; when that is done, it should be primed; but as it would be impossible to do it with loose powder in a storm, a tube is constructed in the simplest manner of common writing paper (the outer edge being cemented with a little gum) in this form (fig. 10). It is filled with meal gunpowder, made into paste with spirit of wine; when in a state of drying, run a needle through the centre, and take care the hole is left open, for, on the tube being inflamed, a stream of fire darts through the aperture with such force as to perforate the cartridge. The mortar should then instantly be fired; and in order to lessen a difficulty that has often occurred in performing this service, a pistol may be used, having a tin box over the lock, to exclude the effect of wind or rain on the priming; and the muzzle being cut [obliquely], dilates the inflammation, so as to require but little exactness in the direction of the aim.

"We will suppose the communication to be secured, although it is scarcely necessary to offer any other assistance than that of a rope, as the inventive genius of a sailor will supply everything else; yet I could expect the people on shore to get a boat ready for meeting the vessel when driven on a beach: it is the promptest and most certain method of relief, as well as the most easy to be accomplished; for by hauling her off with the rope projected, the boat's head is kept to the waves, and not only insures safety by rising to the surge, but prevents her upsetting."

"When the rope attached to the shot (not having barbs to it), is fired over the vessel and lodges, let it be secured by those on board, and made fast to some firm part of the rigging or wreck, that they may haul off a boat by it; but should there not be any boat, then haul on board by the projected rope a larger one, and a tailed block, through which a smaller rope is rove. Let the large rope be made fast at the mast-head, between the cap and the top of one of the lower masts, and the tailed block a little distance below it; but, if the masts should have been cut or carried away, then it must be made fast to the loftiest remaining part of the wreck. When this is done, there will be supplied from the shore a cot, hammock, netting, basket, hoop, or any of the numerous resources of seamen, which will run on the larger rope, and be worked by the people on shore. If a cot be used, the men may be so securely fastened to it as to preclude all possibility of falling out, and then be brought from the wreck, one by one, in perfect safety."

"While communication is gaining, three stakes should

be driven into the ground in a triangular position, so as to meet close at the heads to support each other. As soon as communication has been effected by the crew of the vessel, and they have secured the line attached to the shot, made fast to these stakes, the crew will haul on board by it a large rope and a tailed block, through which a smaller rope is to be rove, both ends of which (the smaller rope) are to be kept on shore. When they have secured these on board, and the larger rope is rove through the rollers, let a gun-tackle purchase be lashed to it, then lash the purchase to the stakes. By the means of the purchase the larger rope may be kept at a fit degree of tension; for, if care be taken to slacken the purchase as the ship rolls out to sea, the danger of the rope being broken will be guarded against; and, on the other hand, if the purchase be gathered in as the ship rolls toward the shore, the slackness of the rope, which would prevent the cot (fig. 11) traversing as it ought to do, and plunge it in the water more than it otherwise would, will be avoided."

Fig. 11.

"Supposing neither boat nor cot apparatus at hand, first cast off the shot from the projected rope, and with a close hitch, let it be put over the head and shoulders of the person to be saved, bringing it close under each arm, drawing it tight, *observing particularly the knot is on the breastbone*; for, by having the knot in that position, on the people of the shore hauling the person from the wreck, he will naturally be on his back, consequently, the face will be uppermost to seize every moment for respiration, after each surf has passed over the body. If circumstances compel recourse to this method, care must be taken to free the rope from any part of the wreck, and to jump clear away; but should there be more than one on board, each man should make himself fast in the same way, about four feet from the other, and join hands, all attending to the same directions."

"For giving Relief to Vessels Stranded on a Lee Shore in a Dark and Tempestuous Night.—It will be requisite, first, to devise the means of discovering precisely where the distressed vessel lies, when the crew are not able to make their situation known by luminous signals; secondly, to produce a method of laying the mortar for the object, with as much accuracy as in the light; thirdly, to render the flight of the rope perfectly distinguishable to those who project it, and to the crew on board of the vessel, so that they cannot fail of seeing on what part of the rigging it lodges, and consequently have no difficulty in securing it."

"To attain the first object, a hollow ball was made to the size of the piece, composed of layers of pasted cartridge paper of the thickness of half an inch, having a lid on the top to contain a fuze (fig. 12), and it was then filled with about fifty luminous balls of star composition, and a sufficient quantity of gunpowder to burst the ball and inflame the stars. The fuze fixed in the ball was graduated, to set fire to the bursting powder at the height of 300 yards. Through the head of the fuze were drilled

Fig. 12

Life-Pre-
servers.

holes, at equal [distances], to pass through them strands of quick match, to prevent the possibility of any accident from the match falling out, or from its not firing the fuze. On the stars being released, they continued their splendour, while falling, for near one minute, which allow ample time to discover the situation of the distressed vessel. During the period of the light, a stand, with two upright sticks (fig. 13), (painted white, to render them more discernible in the dark), was ready at hand, and pointed in a direct line to the vessel.

"A shell affixed to the rope, having four holes in it to receive a like number of fuzes (headed as before described), and filled with the fiercest and most glaring composition, which, when inflamed at the discharge of the piece, displayed so splendid an illumination of the rope, that its flight could not be mistaken."

"To get a Boat from a Beach over the Surf.—The importance of going to the relief of ships in distress at a distance from the land, or for taking off pilots, was viewed as of the highest consequence by the elder brethren of the Trinity House, and offered to my particular attention by several distinguished characters. After numerous experiments to accomplish it in various ways, the mode following was most approved:—About forty fathoms of $2\frac{1}{2}$ -inch rope, made fast to two moving anchors, was laid out parallel with the shore, at a distance beyond the sweep of the surf; to the centre of this rope was made fast a buoy, of sufficient power to suspend the great rope, and prevent it from chafing on the sand, rock, or stones, as well as embedding, a circumstance that has rendered it impossible, on a sandy or shingly coast, to heave out an anchor with a rope to it from the shore. As this service should be performed in fair weather (to be prepared for the storm), it may be regulated with the greatest exactness, and should take place at the top of high-water, that the upper part of the buoy may be at the full stretch of its power, and only seen at that time. Should the shore be extremely flat, it will be desirable to place another set at a sufficient distance beyond the first, to insure the operation of this method in any state of the tide.

"The royal mortar being brought to the spot, is to be pointed in the direction for the buoy, and should be laid at a very low elevation, but such as to insure the range; for the more it is depressed, the less slack of rope there will be from the parabola formed in the shot's flight; the basket with the rope ready laid (having a barbed shot to it) is to be placed in the front of the mortar; on its being fixed, instantly haul the slack of the rope in, to prevent the

Fig. 14.

effect produced on it by a strong tide; which being done, let the remainder be gently hauled in, to insure the shot's

grappling with the great rope; when that is caught and hooked, a power will be acquired fully adequate to the service.

"As a cast-iron anchor appears particularly adapted to this method, and would be much cheaper than hammered, fig. 14 is a plan of one which the Honourable the Navy Board approved, and allowed me to cast at their expense, for the purpose of making the experiment."

"When a vessel is in that extreme and perilous situation, driven under a rugged and inaccessible cliff, and in danger of going soon to pieces, the most prompt method I should suggest is, by lowering to the crew a rope with stiff loops spliced into it (fig. 15), at the distance of a foot and a half from each loop, of sufficient size to contain the foot, by which they can ascend as a ladder.

"This rope-ladder is capable of being projected; and one of an inch and half rope was thrown from a mortar 194 yards. It might also, from the simplicity of its structure, be extremely useful in escaping from a house on fire. By making one end fast to the leg of a bed or a table, the person would come down from the window in safety, and with much less difficulty, and quicker, than with the common rope-ladder, which is heavier and more unwieldy. It has great advantages when employed in saving shipwrecked men in situations just described, when, from extreme cold, and almost benumbed limbs, it would be impossible for them to climb up a rock, or ascend it even by the aid of a common rope. The holds, thus spliced in, will support both hands and feet."

Fig. 15

The Report of the Committee of the House of Commons contains also a paper of instructions for the managers of Captain Manby's apparatus on shore, which are somewhat more minute than the directions published in his Essay. For example:—

"If the wind be sideways to the shore, the mortar must be pointed sufficiently to windwards to allow for the slack of the rope lighting on the object, as the rope will, of course, be borne considerably to leeward by the effect of a strong wind.

"The distance your judgment decides the vessel to be from the shore should regulate the charge of powder as stated in the scale, taking just a sufficient quantity to clear the object: an attention to this will be more certain of your effecting communication, and guarding against the danger of the rope breaking, or any other circumstance that might prevent the successful performance of the service. The elevation of fifteen degrees is to be preferred, particularly if the wind is sideways, pointing the mortar sufficiently to windward, as the rope would then fall against the weather-most part of the rigging of the stranded vessel.

"When a vessel is driven on shore in the night, you will flash gunpowder as often as convenient on your way; this will animate the crew, and denote to them you are coming to their assistance. On getting to the spot where you have reason to suspect the vessel lies, as you are not able to discover her from the extreme darkness, and if the people on board cannot [make known] their situation by luminous signals or noises (which they will be directed to make if possible), you will lay the mortar at a very high elevation, and fire a light ball.

"Just before you fire (the rope) it would be advisable to let off a blue light to put the crew on their guard, to look out, and be ready to secure the rope. The service can be performed with a carronade."

In chap. iv. we have a copy of directions to persons on board vessels stranded on a lee-shore, proposed to be delivered to the masters at the custom-house. It is observed, that even snapping a pistol, when the powder is wet, may sometimes afford a signal visible on shore, from the sparks

Life-Pre-
servers.

Life-Pre-
servers.

of the steel alone. The other parts of the directions will be supplied by those who understand the principles of the proposed mode of relief.

Rockets have of late years been much employed instead of the mortar, in Manby's apparatus for throwing a line to a ship in distress. "Dennett's Rocket Apparatus" is supplied to many stations along the coast. The only advantage which the rocket has over the mortar is its greater portability; for, being much lighter, it can be used with greater facility amongst rocky cliffs, and in positions difficult of access. The disadvantages of rockets are, that they are somewhat uncertain, sometimes exploding as soon as ignited, to the danger of the bystanders; and they are also liable to deteriorate from the effects of damp or of age. Moreover, being expensive, they cannot be often employed in trials, so as to keep up the practice of the people employed in using them. The range of a shot from a 24-lb. mortar, which is the ordinary size, is about the same as that of a 12-lb. rocket, which is the largest in use. As the management of the mortar and rocket apparatus is much better understood by the officers and men of the coast-guard service than by ordinary boatmen and fishermen, it has been almost entirely left in their hands, and is provided by the Board of Customs. There are in England 132 mortar and rocket stations; in Scotland, 15; in Ireland, 22.

Several inventions, or variations, in the Manby apparatus may be just glanced at. M. G. Delvigne uses a howitzer instead of a mortar, while a portion of the line to be carried is contained in the projectile. Mr Greener has a method of discharging a rocket, with a line attached, from a light harpoon gun. When discharged, the rocket ignites, and is said to prolong the range to a greater distance than if the gun or the rocket were alone employed. Captain Jerningham, R.N., has an anchor of a particular form, which he proposes to fire from a Manby's mortar, in sufficient numbers to afford the means of hauling a life-boat through the surf. Mr A. G. Carte employs a war-rocket instead of a Dennett's rocket.

Life-boat.

The last description of the inventions to be considered, with regard to the preservation of lives in cases of shipwreck, is that of life-boats, which are of such a construction as to be incapable of sinking, even when filled with water. The occasional adaptation of the common boats of the ship to such purposes, by means of empty casks, has been already noticed. But the boats now in question are supposed to be kept on shore at proper stations, and manned by active persons, who are in the habit of exerting themselves for the relief of seamen in distress.

Mr Henry Greathead, of South Shields, received a gold medal and fifty guineas from the Society of Arts, in 1802, and a parliamentary reward of L.1200, besides further remunerations from the Trinity House, and from Lloyd's Coffee-House, for his invention of a life-boat, which is described in the *Transactions of the Society*, vol. xx., p. 283. The length of this boat is 30 feet, its breadth 10, and its greatest depth about 3, besides a general curvature, which nearly doubles the depth, as reckoned from the ends; the convexity below being intended to give it a greater facility of turning, and a greater power of mounting on the waves without submersion of the bow, which would increase the resistance, though it would not sink the boat; the breadth is also continued further than usual fore and aft, in order

to contribute to the same property. The gunwale projects some inches, and the sides below it are cased with pieces of cork, amounting in the whole to 7 cwt., which are secured by plates of copper. There are ten short oars of fir, fixed on pins to the gunwales, and a longer oar for steering at each end, both ends of the boat being alike. It is painted white, in order to be more conspicuous; and a carriage is provided, for conveying it overland when required. The description is accompanied by documents of the preservation of 200 or 300 men by the boats of South Shields and North Shields, which were built in 1789 and 1798 respectively.

Mr Christopher Wilson received a gold medal in 1807, for a life-boat with air gunwales, which was tried at Newhaven, and was said to be lighter and more manageable than Mr Greathead's. (*Transactions*, xxv. 55.)

"Little is required," says Captain Manby, "to establish the importance and advantages that will result from giving every boat the properties of a life-boat, particularly when taken into consideration that it can be produced at a very trifling expense."

To illustrate the method of giving the properties of preservation to any boat,—a man of war's jolly boat, for example,—we quote the description of the one which was fitted up to make experiments thereon, by permission of the Honourable Commissioners of the Navy Board.

"To give it buoyancy, empty casks were well lashed and secured in it. For the advantage of keeping it in an upright position, launching from a flat shore, beaching, and to resist upsetting, it had billage boards of equal depth with the keel, and when a good sized piece of iron or lead was let into or made fast to the keel, if any accident did upset the boat, it immediately regained its original posture. A stout projecting rope, with swellings upon it to increase its elasticity, surrounded the gunwale, served as a fender, and prevented it being stoved in lowering down, or when driven in contact with the vessel it might be going to relieve.

"The boat thus described had the plug out, and was filled with water until it ran over the gunwale, when a crew of four, with myself, tried it in every way, and found, from the buoyant property of the casks, it kept the boat so much above the water's edge, that it was rowed with the greatest ease, and was capable of performing any service required."

Mr J. Boyce, in 1814, obtained a medal for his life-boat and safety-buoy, consisting of hollow cylinders made of canvas painted and varnished, and connected with each other. It was tried on a river, and carried a man with safety (*Trans.* xxxii. 177): but surely it could not be trusted among breakers on a lee shore. In 1818 Mr Gabriel Bray obtained a silver medal for his invention of a boat filled with air-boxes under the seats and along the sides. (Vol. xxxv., p. 172.)

Of late years the subject of life-boats has attracted considerable attention, from the circumstance of the increasing number of wrecks, consequent on the rocky nature of our shore, and the vast and increasing amount of our commerce. The exertions, too, of the National Life-Boat Institution¹ have had a powerful influence in directing attention to this subject. The attention of the public is also kept alive by the publication of a journal entitled *The Life-Boat*, which, in addition to statistical returns of shipwrecks, contains information on every subject connected with the preservation of life from shipwreck. One of the publications of the so-

Life-Pre-
servers.

¹ This society, founded in 1824, is under the patronage of her Majesty, and the presidency of his Grace the Duke of Northumberland. The object is to assist every wrecked person in the kingdom, by such means as the establishment of life-boats and rocket-mortars at all the dangerous parts of the coast; to assist in the formation of local committees at the chief ports; to confer rewards in the form of medals, votes of thanks, or pecuniary remuneration to all persons risking their lives for the sake of others; and also to encourage the invention of new or improved life-boats, belts, rocket apparatus, buoys, and other means of saving life. This admirable society is dependent on voluntary subscriptions for its existence and support. That the society has worked with some success, may be judged of from the fact, that since its establishment it has been instrumental in saving the lives of 9682 persons; it has granted 79 gold medals, and 556 silver medals, besides pecuniary rewards, amounting to L.9631.

servers.

ciety is a *Wreck Chart of the British Islands*, originally published by the Admiralty. A vessel wrecked on our coasts is indicated by a black spot ●, while a vessel so seriously damaged as to require to discharge her cargo is indicated by +; and the number of such marks at any one spot indicates the annual average of wrecks, which may be large because the coast is dangerous, or because the traffic is great. Thus, the mouth of the Tyne shows a larger number of black dots and crosses than any other place; the mouth of the Tees and the mouth of the Weir occupy the next places of distinction in this dismal chart: these three rivers being the outlets of the district by which London is supplied by sea with three million tons of coal every year, giving employment to several thousand collier ships, which sail to and fro, and greatly add to the otherwise large trade of the Northumberland and Durham ports. The coast of these two counties indicates per annum 180 wrecks, sinkings, and serious collisions. The mouth of the Humber, the coast of Suffolk between Yarmouth and Southwold, the sandy shoals off the mouth of the Thames, the Goodwin Sands, the Scilly Isles, Barnstable Bay, and Liverpool, rank as the next dangerous portions of the English coast. The Welsh coast is also dangerous, especially Glamorgan, Pembroke, and Anglesea. Scotland, except near the Firth of Forth, is comparatively free from wrecks, the western coast remarkably so, probably from being less exposed to the winds, which tend to drive ships ashore on the eastern coast. In Ireland the E. and S. coasts present about an equal number of wrecks, the smaller number being on the northern and western. In the year 1855 no less than 1141 wrecks occurred on the coasts of the United Kingdom, about one-half of that number belonging to the E. coasts of Great Britain. The loss of life from shipwreck during that year was comparatively small, being only 469, or less than one-third of the loss of the preceding year, the average loss per annum being between 600 and 700 lives.

Passing over a great variety of proposals for life-boats, we proceed to notice the boat which the Life-Boat Institution recommends and supplies to its stations. Its history is interesting. A few years ago, a lamentable accident occurred to a South Shields life-boat, whereby twenty pilots were drowned. This induced the Duke of Northumberland to offer a reward for the best model of a life-boat. This offer was responded to by boat-builders and others from various

parts of the kingdom, as well as from France, Holland, Germany, and America, so that 280 models and plans were sent in. About fifty of the best of these were exhibited by his grace in the Great Exhibition of 1851; and he expressed his intention of placing the best life-boats, with their subsidiary apparatus, on all the exposed points of the coast of Northumberland. He also caused a report to be prepared, accompanied by plans and drawings, with a view to elicit the best form of life-boat; for although the prize of L.100 was assigned to Mr Beeching of Great Yarmouth, it was considered that a better boat might still be produced. Accordingly, Mr James Peake, assistant master-shipwright in H.M. Dockyard at Woolwich, and a member of the Life-Boat Committee appointed by the Duke of Northumberland, was requested to furnish a design for a life-boat which might combine as many as possible of the advantages, and have as few as possible of the defects, of the best of the models examined by the committee. A boat was accordingly designed by Mr Peake, and built at the public expense in Woolwich Dockyard. Some modifications were from time to time made in her, in consequence of various experiments, and a trial of her capabilities made in a gale of wind at Brighton. The boat, with others of the same design, built at the cost of the Duke of Northumberland, was placed on the Northumberland coast in the autumn of 1852. In the course of the following winter these boats were taken afloat on trial by the Society's inspector of life-boats, some of them in heavy seas and gales of wind, and the result of the trials was considered to be highly satisfactory. Other boats were therefore built on the same plan, and we may therefore consider this as the model life-boat. These boats have been for the most part of two sizes, viz., 27 and 30 feet in length, with $7\frac{1}{2}$ to 8 feet beam, and rowing from eight to twelve oars, double-banked; their weight averaging two tons. But as such boats have been found too heavy to be managed in some localities, where boatmen are few, boats of less beam and weight, rowing six oars single-banked, but on the same design in other respects, have been built under the denomination of second-class life-boats. The former class of boats have also been somewhat modified since the description of the boat was first published, so as to be reduced somewhat in beam, and to have less height, and greater sharpness of bow and stern, to enable them to be rowed with greater speed against a head gale and a heavy

Fig. 17.

sea. They are also built of fir, upon the diagonal principle of double planking without timbers, whereas the earlier

boats were of elm, and clenched, or clinker-built.

The accompanying figures show the general form and the

Life-Preservers.

Life-Preservers.

nature of the fittings and air-chambers of one of these boats, 30 feet in length, and 7 feet 6 inches in breadth. In figs. 16 and 17, corresponding to the elevation and deck-plans, the general exterior form of the boat is seen, showing the sheer of gunwale, length of keel, and rake, or slope of stem and stern posts. The dotted lines of fig. 16 show the position and dimensions of the air-chambers within board, and of the relieving tubes. A represents the deck, B the relieving tubes, 6 inches in diameter, C the side air-cases, D the end air-chambers. In fig. 18 the exterior form of transverse sections, at different distances, from stem to stern is shown. Fig. 19 represents a mid-ship transverse section, A being sections of the side air-cases, B the relieving tubes, bored through solid massive chocks of wood of the same depth as the space between the deck and the boat's floor; C, C are spaces beneath the deck filled up, over 6 feet in length, at the mid-ship part of the boat, with solid chocks of light wood, or boxes of cork, forming a portion of the ballast; D is a section of a tier below the deck, with a moveable hatch or lid, in which the boat's cable is stowed, and into which all leakage beneath the deck is drained through small holes with valves fixed in them. In some of the later boats a small draining tier only is placed, having a pump in it, by which any leakage

Fig. 18.

Fig. 19.

can be pumped out by one of the crew whilst afloat. The festooned lines in fig. 16 represent exterior life-lines, attached round the entire length of the boat, to which persons in the water may cling until they can be got into the boat; the two central lines are festooned lower than the others, to be used as stirrups, so that a person in the water by stepping on them may climb into the boat.

The chief peculiarity of a life-boat is its incapability of being sunk, in consequence of its being fitted with water-tight air-cases, or compartments. One of the difficulties of life-boats has been to decide as to the amount and distribution of such air-cases. The necessary space for rowing and working the boat, and for the stowage of shipwrecked persons being secured, the spare space along the sides within-board should be entirely occupied by buoyant cases, or compartments, because, on the boat's shipping a sea, the water, until got rid of, is confined to the midship parts of the boat, where it serves to a great extent as ballast, instead of falling over to the lee-side, and destroying the equilibrium of the boat. Hence, barrels or casks, which do not conform in shape to the sides of the boat, are not well adapted to serve as air-cases. In Mr Peake's life-boat there is a water-tight deck at the load-water-line, and detached air-boxes along the sides, closely conforming to their shape from the thwarts to the deck. Extra buoyancy is also derived from large end air-cases, built across the bow and stern, and occupying from 3 feet to 4½ feet in length, from the stem and stern posts to gunwale height. These cases are chiefly intended to provide self-righting power; but in the event of the boat being stove in, and the space below the deck being filled with water, these air-cases alone have sufficient buoyancy to float the boat.

The second peculiarity of a life-boat is its power of discharging, in a few seconds, any water which may be shipped by the breaking over of the sea, or by the boat being suddenly thrown on her beam-ends. This property does not belong to all life-boats, for, in certain cases (the Norfolk life-boats, for example), the plugs which stop up certain holes in the floors are taken out during a gale of wind, or a heavy sea, so as to let the water into them until it is

at the level of the sea. The water thus let in is confined by the wide side-cases to the mid-ships of the boat, where it serves as a loose ballast, and the boatmen consider that it is safest to go off under sail with the boat deeply immersed. The Liverpool life-boats have no relieving holes, so that when filled by a sea, the water must be got rid of by baling. In Mr Peake's boats there is a water-tight deck at the load-water-line, and a number of large open tubes, opening at the surface of the deck, and passing through the space between the deck and the floor; the bottom orifices being furnished with self-acting valves opening downwards, so as to allow any water shipped to escape through them. The deck being placed at or above the load-water-line, any water which is above it will be above the outside level of the sea, so that the water escapes from the deck by its own weight, and disappears in a few seconds.

As a life-boat has very great buoyant power, it is important to her stability and safety to attend to the ballasting. The Greathead life-boats have usually no ballast, their great breadth of beam being relied on for stability; but some of them have a tank in the midships beneath the deck which can be filled with water. Beeching's life-boats are similarly ballasted; but accidents, with loss of life, have arisen from a difficulty in filling the tanks, and preventing the escape of the water when full; hence solid ballast is to be preferred. Mr Peake's life-boats are ballasted with heavy iron keels, and with solid wood and cork ballast, stowed under the decks; and should these be stove in, and the space beneath be filled with water, the wood and the cork would supply extra buoyancy.

A life-boat ought to be self-righting if upset, a property which, however, belongs only to Mr Peake's and Mr Beeching's boats, some boat-builders considering that stability is sacrificed thereby. The fact, however, has been established in the *Life-Boat Journal*, that the means employed to produce self-righting add to the stability of a boat, and improve her in other respects. The self-righting power is thus attained;—“1st. The boat is built with considerable sheer of gunwale, the bow and stern being from 1 ft. 6 in. to 2 ft. higher than the sides of the boat at her centre, and the space within the boat at either extremity, to the distance of from 3 to 4½ ft. from the stem and stern posts to gunwale height, is then inclosed by a sectional bulk-head and a ceiling, and so converted into a water-tight air-chamber, the cubical contents of which, from the thwarts upwards, are sufficient to bear the whole weight of the boat when she is placed in the water in an inverted position, or keel upwards. 2d. A heavy iron keel (from 4 to 8 cwt.), is attached, and a nearly equal weight of light wood or cork ballast is stowed betwixt the boat's floor and the deck. No other measures are necessary to be taken in order to effect the self-righting power. When the boat is forcibly placed in the water with her keel upwards, she is floated unsteadily on the two air-chambers at bow and stern; whilst the heavy iron keel and other ballast being then carried above the centre of gravity, an unstable equilibrium is at once effected, and the weight of the iron keel falling over on one side, immediately restores the boat to her proper position; in other words, she self-rights” (*The Life-Boat*, No. 22).

Lateral stability or stiffness, being the tendency to preserve an upright position in the water, with proportionate resistance to upsetting, is obtained by breadth of beam or by ballast—as in Mr Peake's boats, by an iron keel and other solid ballast, and by flatness and length of floor, with moderate beam only. The other qualities to be required in a good life-boat are speed, strength, and stowage-room, all of which seem to have been well-considered in Mr Peake's boats.

A new description of life-boat, invented by the Rev. E. L. Berthon, M.A., of Fareham, and known as the Fareham Life-boat, has been made the subject of a patent. Its novel feature is, that it is collapsible, so that it combines the pro-

Life-Pre-
servers.

perty of the life-boat, with facility of stowage in a small space. Hence, it is well adapted for the use of ships, especially large steamers, emigrant vessels, and troop-ships. Its frame-work is of wood, all the timbers extending the whole length of the boat, there being no transverse timbers or ribs. The timbers, four on each side of the stem and keel-piece, are thin, flat, and deep, something like a thin slice of melon; they are made without scarfing, by bending plank over plank till the required thickness is attained. They are jointed together at their ends, and to the tops of the stem and stern posts by a kind of chain hinge. When the boat is collapsed, these timbers stand side by side in vertical planes, like the leaves of a closed book; but when expanded, they stand apart in radial planes, somewhat like the segments of an orange. Attached to the edges of all the timbers are the water-proof coverings, of which there are two, the outer skin being secured to the outer edges, and the inner skin to the inner edges of the timbers, by which means the whole body of the boat is divided into eight separate longitudinal cells or compartments, which become filled with air on expanding the boat. This is effected and maintained by the bottom boards and thwarts, which being jointed along the middle line, are made to stand up at an acute angle when the boat is collapsed, and fall down to straight lines when open. The inventor compares the principle of extension to that of a carriage-head, the frame of which may be compared to the boat's timbers, and the joints to the thwarts and stretchers of the bottom boards; and as the leathern covering of the carriage shuts in when the head is down, so the coverings of the boat shut in between the timbers. The boat has rather a deep keel, besides two bilge pieces on each side, and in every other salient point the covering is protected by wood or copper. The boat is lowered by the following contrivance:—Inside the bulwarks is a large, flat, deeply-grooved sheave about 2 ft. 6 in. in diameter; it has two deep, narrow grooves cut nearly to its axis, and in these are wound separately the ends of the two falls. From this sheave is a projection on which a friction-strap with a powerful lever is made to work. This being placed flat against the bulwarks, the falls are brought to it fore and aft by small sheaves set in the top-rail: thus the friction of the strap when the boat is up is enough to prevent motion; but by slacking the lanyard by which the lever is secured, it may be allowed to descend rapidly or slowly, according to the pressure applied to the break. Rising and falling derricks are substituted for davits.

The average size of the Fareham life-boat is 32 by 10 ft., it has eight thwarts, besides seats round the stern, and will pull, if required, twelve oars double-banked.

Captain Manby's proposal for throwing ropes from ship to ship in cases of accidents may easily be understood from the methods which he employs for saving lives in shipwrecks. The life-buoy for Lieutenant Cook, R.N. F.R.S., Professor of Fortification at Addiscombe College, is related to the same class of inventions; its object is to preserve the life of a person falling overboard in the night, by means of a floating light; and it obtained him a gold medal from the Society of Arts in 1818. (*Transactions*, xxxvi., p. 121.) He observes that a ship may often have to run half a mile before she can get about and lower a boat, so that it becomes highly desirable to afford a temporary support to the sufferer. The machine consists of two copper spherical air-vessels, with a square tapering tube through each, made water-tight, and united together by a cross piece of wood, in which are two brass conducting tubes through which is fixed a perpendicular tubular-staff, with a brass ferule at each end, and a copper sliding rod, nearly its own length, within it. Attached to the lower end of the rod is a flat circular balance-weight, bearing a chain by which the life-buoy is suspended, and a link which, when hooked to a stud

in the lower ferule, bears up the rod and the balance-weight, but which, when unhooked, allows the weight to draw the rod about two-thirds out of the staff. To the head of the perpendicular staff is attached at night a fuse, on a brass fuse-plate, the shank of which is secured into a socket by a thumb-screw. The buoy is secured to the ship by the chain only, the ring of which hangs on the hook of the sheave of the trigger-plate. Attached to the stern of the vessel are two iron rods cased with copper tubing, together with the screw-bolts, from which they are suspended; just above the forked stay which keeps the rods parallel, at a proper distance from the stern, is the trigger-plate, and the brass fuse-case which covers and protects the fuse on the head of the staff. There is also a brass case for the lock or percussion hammer, placed so as to communicate with the fuse-case, by means of the horizontal tube; all these, together with the pulleys and guard-iron are, firmly attached to the stern of the vessel, inside of which, immediately opposite to the pulleys, are fixed the cups and handles, the one for firing the lock and lighting the fuse, the other for raising the trigger-bolt and disengaging the buoy from the ship. As soon as the trigger-bolt is raised, the sheave revolves, the stop turns round, and the life-buoy slides off the rods into the water, bearing on the head of the staff a brilliant flame. The balance-weight, when no longer held up by the chain, drops upwards of 3 feet below the cross-piece, prevents the buoy from upsetting, and affords a place for the man to stand on. This apparatus admits of being lighted and let down into the water in the short space of five seconds. Lieutenant Cook is also the inventor of a plan for converting boats used for ordinary purposes into life-boats at pleasure.

Mr Miller's safety-poles for skaters, and Mr Prior's mode of preventing accidents in descending mines, are mentioned in the *Transactions of the Society of Arts* (vols. xxxii. and xxxvi.) Apparatus of the latter kind has been introduced at different times with various modifications. In coal-pits, or coal and iron pits, where the men are raised and lowered in a rectangular iron frame called a cage, the rope or chain may break, or the cage may be overwound by drawing it over the framing at the pit's mouth. Mr Robert Blee of Redruth has introduced what he calls a safety-bucket, and Messrs White and Grant of Glasgow have a safety-cage. These inventions depend upon some such arrangements as the following:—Two pairs of eccentrics are attached to the ends of two parallel shafts, which extend across the top of the cage; the edges of the eccentrics are toothed, and when the cage is in motion they are free of the vertical wooden rails which steady the cage in its motion up and down the pit. Should the rope break, two volute springs bring round the thick sides of the eccentrics to bear against the guides, and hold the cage securely. To prevent over-winding, the holdfast which connects the rope to the cage is secured by a curved bolt, kept in place by a strong spring; this bolt moves on a fulcrum, and is continued as a lever beyond the holdfast; across the framing at the mouth of the pit is a bar so arranged that, when the lever comes in contact with it, the bolt becomes disengaged, the cage by the action of the eccentrics becomes fixed, and the rope only is drawn up over the pulley. In Mr Blee's safety-cage the catches allow it to move freely so long as there is a vertical strain on them; but should this cease by the breaking of the rope, the catches become liberated and attached to the iron staves of the ladders placed on either side of the shaft.

A sketch of the expedients which have been recommended for the preservation of mariners, published in a work entitled *Shipwrecks and Disasters at Sea* (vol. iii., p. 459, Edinb. 1822, 8vo), contains a few further historical details relating to some of the inventions which have been described.

Light.

SECT. I.—HISTORY OF THE SUBJECT.

THE nature and properties of the agent on which vision depends have been objects of philosophical disquisition from ancient times. The earliest speculations which have reached us on this subject are those of Pythagoras, who considered vision as produced by particles continually emanating from the surfaces of bodies, and entering the pupil of the eye. The Platonists, on the other hand, conceived that vision was the consequence of the emission of something from the eye meeting with certain emanations from the surfaces of things; yet, with this very gratuitous hypothesis, they appear to have detected several properties of LIGHT, especially its propagation in right lines, and the equality of the angles of incidence and reflection when it falls on bright and polished surfaces. The effects of the concentration of the sun's rays by concave specula were certainly known to the ancients. Antiquaries have accordingly supposed, that, in this manner, the Romans kindled their *sacred fire*; and thus also it has been alleged that Archimedes destroyed the Roman fleet at the siege of Syracuse.

Aristotle regarded light but as a mere quality of matter; and he has some ingenious speculations on the rainbow, and on other luminous meteors. Ptolemy the geographer wrote a treatise on optics, which has perished; but, from some fragments preserved by other authors, he appears to have had distinct ideas on the subject of atmospherical refraction.

A long interval of darkness succeeded his era of speculation, until the Arabians began to cultivate the learning of the Greeks, and several of their philosophers treated of optics. But the earliest Arabian work which has reached our times, is the celebrated treatise of Alhazen. In it we find a description of the eye, and of the uses of its different parts. The author details many experiments on refraction, both as exhibited in the atmosphere, and as regards the modifications of light in passing from one medium to another of different density. He likewise notices the magnifying power of segments of spheres of glass; a hint from which it has been supposed that the important invention of *spectacles* originated. We also owe to him the idea that single vision, with two eyes, is produced by images painted on corresponding points in each retina; and that stars may be seen by refraction, when they are actually below the horizon; remarkable speculations for the twelfth century.

The work of Alhazen was in 1270 commented on by Vitellio, a native of Poland, who added a considerable number of observations on the refractive power of air, water, and glass, which he reduced into a tabular form. He made some ingenious attempts to explain the phenomena of refraction; and he seems to have conceived the true idea of burning lenses.

Roger Bacon, the contemporary of Vitellio, was undoubtedly acquainted with the magnifying property of segments of spheres, and recommended that small segments should be preferred for such purpose; adding, *et ideo hoc instrumentum est utile senibus et habentibus oculos debiles*. This so plainly indicates the invention of spectacles, that we cannot doubt that it had then been made. We know that they became common in the thirteenth century, and are described by Spina of Pisa in 1313, although we have no absolute certainty as to the person who first constructed them.

After the revival of letters, one of the earliest cultivators of mathematics was Maurolycus of Messina, who made

optics his study. He proved that the crystalline lens of the eyes of animals converges the rays of light which enter that organ, and transmits them to the retina, in or near which the foci of the lenses are situated. Hence also he inferred, that in persons who are *short sighted*, the defect is owing to the too sudden convergence of the pencil of rays before the retina; and that in those who are *long sighted*, the foci are placed behind that expansion of the optic nerve. Maurolycus, however, did not discover that the images of objects are painted on the retina.

Baptista Porta, the author of *Magia Naturalis*, a Neapolitan of rank, was much addicted to philosophic research; to him we owe the first description of the camera obscura, and its application to the delineation of objects. His work contains many observations on light, some of which are accurate; and though some are now found to be erroneous, his remarks are always ingenious. This subject also engaged the attention of Lord Bacon, who complained that the *form* and *origin* of light had been too much neglected; but his labours in other branches of philosophy diverted his powerful mind to different objects.

The true theory of the rainbow was first given by Antonio, bishop of Spalatro, although he could not satisfactorily explain the cause of the colours.

The next optical discovery of importance was the *telescope*, for which we are indebted to Zacchias Jansen, a spectacle-maker of Middleburg, in Walcheren, in 1590; and this important invention was quickly applied by Galileo to physical astronomy, with brilliant success, crowned by the discovery of the satellites of Jupiter, the structure of the Via Lactea, the phases of Venus, the ring of Saturn, the spots on the sun's disk, and a knowledge of numerous stars unknown to former observers.

The study of light was improved under the auspices of Kepler, who gave an explication of the effect of lenses on the rays, and suggested the form of the telescope now called *astronomical*. He treated of refraction, and discovered, that when light falls within glass at an angle a little above 42° , it is wholly reflected. But his theory of vision is much more important; for he showed that images of external objects are painted on the retina, and appear there inverted, a fact also ably illustrated by Scheiner. The invention of the compound microscope seems also due to Jansen, and dates from the same period.

Perspective was first scientifically treated by Pietro del Borgo, Baldassare Perussi, and Guido Ubaldo. To the second of these is due the detection of the *distance points*, to which all lines forming an angle of 45° with the *ground line* are drawn; to the third, the convergence of all parallel lines inclined to the ground line, in a point in the *horizontal line*, and also that a line drawn from the eye, parallel to them, will pass through this point. These principles are the foundation of perspective, which afterwards received improvements from 'sGravesande, and were completed by Brooke Taylor. The true law of refraction is undoubtedly due to Willebrod Snell, or Snellius, professor of mathematics at Leyden. He experimentally showed that the co-secants of the angles of incidence and refraction are always in the same ratio. This discovery, we are assured, on the authority of Huygens, was appropriated by Descartes, who had consulted the papers of Snell, but gave it as his own, under a somewhat different form. The successive labours of Descartes, Kircher, Grimaldi, De la Hire, Hooke, and Huygens, gave to the study of optics a profound scientific character; and the interesting discoveries of that century were crowned by the important researches of our immortal

Light.

Light. Newton concerning the optical properties of light. During the last century, our knowledge of this subject has been steadily progressive, by the labours of a multitude of philosophers, so numerous, that we can afford space for little more than to record the names of some of the most successful inquirers into the mysteries of this subtle agent. Amongst these, Mairan, Dufay, Mariotte, Boscovich, Euler, Mitchell, Melville, Canton, Bennet, and Lagrange, stand conspicuous; nor must we omit the important fact, illustrated by the labours of Bradley and Roemer, that the velocity of light, from whatever source derived, whether from the sun, the fixed stars, the planets or their satellites, is equal, or that its velocity before and after reflection is the same; a formidable objection to the theory of emission. During the present century, the progress of discovery in this field has been no less brilliant. Very early in it, Dr Thomas Young illustrated the principle of the *interference of the rays of light*, founded on some facts observed by Grimaldi, but first distinctly stated in Dr Young's Memoir in the Philosophical Transactions for 1803, entitled *Experiments and Calculations relative to Physical Optics*; and his conclusions have been demonstrated beyond all doubt by the researches of Fresnel and of Sir John Herschel. The splendid talents of Laplace, of Poisson, Biot, Arago, Pouillet, Cauchy, Ampère, and Fresnel, amongst continental philosophers, have especially illustrated the phenomena and theory of light; and in our own country, Sir William Herschel, Young, Brewster, the younger Herschel, Airy, and Whewell, have pursued these delicate investigations with singular ability and success. Above all, we must record, as amongst the most signal triumphs of modern science, the detection and explanation of the *polarization of light*, and the singular confirmation thereby afforded of the theory of its propagation by *undulations*. See SIXTH DISSERTATION.

SECT. II.—NATURE OF LIGHT.

Notwithstanding this long list of splendid discoveries, the nature of light is still in some degree enigmatical. It is admitted, that the phenomena of vision depend upon the agency of a subtle, extremely attenuated matter, set in motion by the sun and other luminous bodies. Its materiality is inferred from its deflection from its rectilinear course, in passing near various bodies; from its being arrested by certain substances, though it passes freely through others; from its reflection by polished surfaces; from its capability of condensation and dispersion, in passing through certain media; from its producing chemical changes in certain compounds; and from its apparently entering into the composition of some bodies, from which it may be again extricated.

Thus far the majority of philosophers are agreed; but two opposite theories have been advanced respecting its propagation, and the mode in which it manifests itself to our senses.

Some maintain that light is a peculiar matter, which is projected in all directions from luminous bodies in a rapid succession of material particles. This theory is sustained by the illustrious name of Newton, and has been very generally received; but of late, certain difficulties in the explanation of the recently-discovered properties of light, especially its polarization, have tended to revive the doctrine maintained by Descartes, Huygens, and Euler, viz. that all the phenomena of light depend on the *undulations* of a highly attenuated fluid or ether, universally diffused throughout space, which, while at rest, is inappreciable by our senses, but, when acted on by luminous bodies, is thrown into a succession of waves. Luminous bodies are thus supposed to act on the universally diffused fluid somewhat in the same manner that sonorous bodies do on air in the production of *sound*.

Light. It is true, that all the known facts regarding light may be explained upon either hypothesis. It must be owned, however, that the remarkable coincidence of fact with theory, and the facility of explanation, favour the theory of undulations, whilst it scarcely can be said to involve any greater assumption than the doctrine of direct transmission. Both assume the existence of a subtle fluid; both admit the influence of luminous bodies; and it does not seem more difficult to conceive them acting, by causing an undulation in the *matter of light*, than by projecting it in a rapid succession of particles, the minuteness and velocity of which almost elude the grasp of our imagination.

Whichever hypothesis we adopt, the propagation of light is a process of astonishing rapidity. Astronomers have found, from observations on the eclipses of Jupiter's satellites, that planetary light requires about fourteen minutes to cross the earth's orbit; or, if we adopt the more recent and probably more accurate determination of Bradley, that the light of the sun requires about eight minutes to reach our earth; and, if we reckon the mean distance of the sun to be 94,879,956 English miles, it follows, whether we regard it as an emanation or an undulation, that light must travel with a velocity of about 200,000 miles per second.

It is difficult to form any adequate idea of such enormous velocity; but we may approximate it, by comparing this with the ascertained velocity of a cannon ball. A twenty-four pounder, with the common charge of powder, according to Robins, discharges its ball with an initial velocity equal to 1600 feet per second; yet, if such a ball were to continue this velocity undiminished, it would require about ten years to traverse a space which the light of the heavenly bodies pervades in eight minutes.

This prodigious rate, and the ease with which light can penetrate many solid bodies, have been adduced as arguments against the doctrine of the successive emanation of particles from luminous surfaces; but did not the undulatory theory afford an easier solution of certain recently-discovered properties of light, we should not regard such arguments as conclusive. Now, however, the undulatory theory has been shown to correspond so exactly with known facts, and has even enabled us to predict so exactly what experiment has since confirmed, that it has received the sanction of the greatest names in modern science. See CHROMATICS.

SECT. III.—PROPERTIES OF LIGHT.

Whichever hypothesis be adopted, light must be considered as a material substance, possessed of certain properties, detected by observation and experiment.

1. Light is given out by luminous bodies in all directions, and from every point of the luminous surface. This is proved by its being equally seen from every point of observation.

2. It is divisible into homogeneous, independent portions, like air or water; the smallest portion we can separate is termed a *ray*; and several rays form a *pencil of light*.

3. Light appears to be absorbed by certain bodies, and is again given out by them spontaneously. This property is well seen in the diamond, which, after being exposed to the sun's rays, continues for a short time to shine in the dark. Various artificial *phosphori* do the same, as the Bolognian stone, calcined oyster shells, and the like.

4. All solids give out light when heated between 700° and 800° of Fahrenheit's thermometer, and are then said to be *incandescent*. All liquids that can be heated to that point are luminous, as melted metals; and, if the elasticity of their vapours be repressed, other liquids appear capable of this emission. Gases do not, however, seem to be capable of incandescence, yet the phenomena attending their sudden condensation, when they enter into chemical union,

Light. shows that they contain light. Thus, when a mixture of oxygen and hydrogen is suddenly and strongly compressed, the gases unite to form water, and both light and heat are extricated.

5. Some bodies have the property of arresting the progress of light, and are termed *opaque*; others transmit it, and are said to be *transparent*. Yet probably no substance is either perfectly opaque or perfectly transparent. Thus, gold is one of the most condensed and opaque bodies in nature; yet if we enclose gold leaf between two plates of glass, and examine it by transmitted light, it appears of a decidedly greenish hue, showing the transmission of some light through the metal. On the other hand, the most transparent glass, when viewed in a thick plate, and the most limpid water, when in a deep column, appear greenish.

6. When the rays of light fall obliquely on the surface of all bodies, whether transparent or opaque, solid or fluid, they are more or less reflected. Smooth and shining surfaces reflect most light, but the degree also depends on the nature of the reflecting substance. The reflected rays are returned from the surface at an angle equal to the angle of incidence; and if the reflecting surface be a plane, the parallel rays that fall on it are reflected parallel to each other.

When the rays are reflected from a concave surface, the reflected rays are more inclined to each other than the incident rays; and if that concave surface be the segment of a sphere, the parallel incident rays will converge to a point in the axis of the mirror half way between its surface and the centre of the sphere of which it is a segment; and this point is termed its *principal focus*, or focus of the parallel rays. If the incident rays be *converging*, they will meet the axis between the principal focus and that centre; if the incident rays be *diverging*, they will meet the axis in a point between the principal focus and the surface of the mirror. From the immense distance of the sun, all the incident rays may be considered as parallel; and therefore his rays will be condensed into the principal focus of such a mirror, which will in this instance also be that of greatest heat. This is the principle of burning mirrors. When the incident rays fall on a convex mirror, they are all reflected more divergingly, or are dispersed.

The properties of reflected light form the object of the science of *Catoptrics*. See OPTICS.

We are not, however, to imagine that all the light incident on bright surfaces is reflected. Many curious experiments were made on this subject by M. Bouguer. The quantity of light returned differs with the inclination of the rays to the reflecting surface. It is generally strongest at small angles of incidence; and the difference becomes excessive when the rays impinge on the surface of transparent fluids with different degrees of obliquity. Metals, from their opacity and splendour, form the best reflecting surfaces; but even pure mercury, perhaps the most perfect of reflectors, does not reflect more than three fourths of the whole incident light.

7. When the rays of light fall on transparent bodies, they are differently affected, according to the angle of incidence. When a ray passes from one transparent medium to another, in a direction perpendicular to their touching surfaces, that ray will pass through them in a straight line; but when the ray passes in a direction oblique to their touching surfaces, that ray will be bent, or will form an angle at their junction.

When the density of a medium is uniform, the rays of light traverse it in straight lines; but in a medium varying in density, like columns of liquids, or the atmosphere, in which density increases with the superincumbent pressure, the passage of the rays will form curves.

When a ray passes obliquely from a dense to a rarer medium, it is bent or deflected *from* a line perpendicular to their contiguous surfaces. When passing obliquely from a

rare to a denser medium, they are bent *toward* the perpendicular. In such instances the light is said to be *refracted*. In the first instance, the angle of refraction is always greater than the angle of incidence; in the latter it is always less. The study of the properties of refracted light constitutes the science of *Dioptrics*. (See OPTICS.)

8. The refractive power of different media is unequal; and when the rays of light pass from one medium to another, it may be measured by the ratio between the *sines of the angles of incidence and refraction*; and the number expressing the ratio between the first and the last is the *exponent* or *index* of the refractive power of that substance.

The refractive power of different substances appears to be nearly in the ratio of their density; but with inflammable bodies, or those containing an inflammable principle, the refractive power is in a ratio greater than their density. It was this law which led Newton to his happy conjecture that *water* and the diamond might contain an inflammable principle; speculations which have been verified by modern chemistry. The same opinion as regards the diamond was long before maintained by Boetius de Boodt. He says that unctuous and fiery bodies are easily united, but will not mix with watery substances; and because the diamond readily adheres to resins, which are of a *fiery* nature, and because, like amber, another fiery body, the diamond, when rubbed, attracts light bodies, the diamond itself must be of an inflammable or sulphureous nature; an argument which he considers as confirmed by that gem being "produced in a hot, sulphureous climate." It is obvious that the deduction of Newton differs widely in its principles from the hypothesis of De Boodt; but the latter must be regarded as a curious instance of a true conclusion derived from unsound premises.

9. If a pencil of light be admitted by a small hole in the window-shutter of a darkened room, through a triangular prism of any transparent substance, the white light will be found to undergo a remarkable change. The rays will be separated in the prism; their image will be enlarged; and, if received on a white screen, they will be seen variously coloured. The colours will assume a certain determinate order of juxtaposition; and this appearance has been termed the *prismatic spectrum*. This coloured spectrum will then be seen divided into colours, of which Newton enumerates seven; red, orange, yellow, green, blue, indigo, violet. These, it is evident, may be resolved into red, yellow, and blue; for the boundaries of the colours are not well defined, and the compound colours which lie between these may be considered as made up of the intermixture of contiguous rays. These rays are not in equal proportions in the spectrum. If we consider it as divided into 360°, the red occupies 45°, the orange 27°, the yellow 48°, the green 60°, the blue 60°, the indigo 40°, the violet 80°; and it is worthy of remark, that this division of the scale of colour is a striking approximation to the divisions of a chord that would give the musical intervals of the octave. But as these colours are not bounded by defined lines, but graduate into each other, it is very difficult to determine their relative extent with tolerable precision. The cause of their separation is the difference of their refrangibility by the prism; the red being the least, the violet the most refrangible, that is, turned from the line of the incident pencil of light. The green ray will be found in the centre of the prismatic spectrum; and hence its index of refraction is considered as the mean refraction of the substance of which the prism consists. Newton employed in his experiments prisms of different substances; but he seems to have taken it for granted, that when the mean refraction was the same, the length of the spectrum was also equal, or that the *dispersive power* of the bodies in that case was equal. He considered that prisms and lenses of every kind of glass,

Light.

Light and of all bodies, whether solid or fluid, with the same *mean refraction*, possessed also the same *dispersive power*, or formed spectra proportional to their mean refraction. Hence he was led to conclude that "the improvement of the refracting telescope was desperate." This error has, since his day, been detected; and the principle discovered forms the basis of Dollond's admirable invention of the *achromatic telescope*, in which the error of refraction in one species of glass is ingeniously remedied by a correction derived from the different dispersive power of another kind of glass, so adapted to the first as to form with it one object-glass. The difference in dispersive power has now been ascertained in a considerable number of diaphanous bodies; and tables of this difference have been formed from the observations of many philosophers, particularly of Sir David Brewster. See CHROMATICS.

The illuminating power of the different rays of the spectrum is different. Sir William Herschel found, that with a prism of flint-glass, the greatest illumination is towards the middle of the spectrum; the yellow rays affording most light, whilst the illuminating power, diminishing towards each end of the spectrum, is least in the violet ray. A series of experiments on this subject by Fraunhofer, a late celebrated instrument-maker of Munich, showed, that with the best made prisms, when other light is carefully excluded, the most luminous point is nearer the red than the violet end of the spectrum, in the proportion of one to four; and he states the mean refrangibility to be between the blue and indigo rays. But one of the most curious discoveries of this ingenious inquirer is, that the solar spectrum is traversed by numerous dark lines of unequal thickness, perpendicular to the length of the spectrum, and parallel to one another. These lines require a fine prism for their exhibition, a microscope for their detection, and the exclusion of light, except that of the coloured ray under examination. He counted 590 of these lines in the spectrum; the greatest number of them being towards the most refrangible end of the spectrum.

It is well known that the rays of the sun communicate heat as well as light; but the heating power of the coloured rays is very different. Herschel discovered that the red ray raises the thermometer most; and that the effect diminishes as we approach the other end of the solar spectrum. This is sufficiently striking; but in pursuing his investigations he made another singular discovery, that the point of greatest heat is fully half an inch beyond the red end of the prismatic spectrum. Delicate thermometers were placed in the different rays, and gave the following results:—

In the blue ray in	3 minutes it =	56° F.
Green.....	3	... = 58°
Yellow.....	3	... = 62°
Middle of the red.....	2½	... = 72°
Outer confines of red.....	2½	... = 73° 5'
Half an inch beyond the red.....	2½	... = 79°

These curious experiments were confirmed by Sir Henry Englefield and Sir Humphry Davy. The inference from them is, that light and heat are unequally refracted.

The prisms used by these philosophers appear to have been of flint-glass; but Dr Seebeck has since found that the position of the point of greatest heat varies with the nature of the refracting prism. Seebeck found, as Herschel did, that with flint-glass the greatest heat was beyond the red; with plate-glass, in the middle of the red; with sulphuric acid in a hollow thin glass prism, in the orange; with water, in the yellow. The sun's rays would appear to be still more complex. Early in this century, Ritter of Jena found that the rays of the solar spectrum possessed different chemical powers. He found that the salts of silver became soonest black a little beyond the violet end of the spectrum, a little less so in the violet, and still less so in the

blue; and Seebeck, in repeating the experiments, found that beyond the violet ray muriate of silver became reddish brown; in the blue, bluish gray; and in the yellow it retained its white colour, or at most had a yellowish tint; it became reddish in the red ray, and even when placed beyond it. These changes might have been attributed to the influence of heating or illuminating power, had not the greatest deoxidating effect been observed where the heat and illumination are the least. Dr Wollaston, who observed these facts about the same time with Ritter, considers the sunbeams as compounded of calorific and deoxidating as well as luminous rays, all with different degrees of refrangibility. But if the experiments of Morichini be confirmed, the sunbeams have also the property of magnetizing steel. In the year 1813 he announced this discovery; it was repeated by several persons without success, but Mrs Somerville appears to have succeeded. She covered one half of small sewing needles with paper, in Morichini's method, and exposed the naked half to the violet rays for two hours, when she found that the needle had thus acquired a north pole. The indigo ray produced nearly the same effect, but the effect was feeble in the blue and the green; whilst, though exposed in the orange, yellow, and red, for two successive days, no magnetism was induced. Similar effects followed when one half of the needle was enveloped in white paper, and the other half, exposed to the rays, was covered with blue or green glass, or with silk of those colours.

10. The facts already noticed respecting the bending of the rays toward the perpendicular, when they pass from a rare to a denser medium, lead to the inference that the disposition of the surfaces of the refracting medium must materially influence the direction of the rays of light which enter and pass through. Accordingly, it is found that if one or both surfaces be convex, the rays are bent toward the axis of the medium. If the medium be spherical, or a segment of a sphere, the ray, falling perpendicularly on its centre, will pass straight through; but all those that fall obliquely on the spherical surface will emerge from the medium in a direction inclined to the central ray (which may be considered as the *axis* of the medium), and will cut this axis in some point, which is termed the *refracted focus* of those rays. When the medium has its surfaces forming segments of spheres, it is called a *lens*; and lenses are divided into convex and concave, plano-convex and plano-concave, double convex and double concave, according to the form of their surfaces.

When a lens is nearly or really spherical, optical principles will show, that all the emergent rays will not meet in the same point, and that those farthest from the axis will meet first. But if the lens be a thin segment of a sphere, with one or both of its surfaces convex, this error will not be very conspicuous, and the emergent rays will meet nearly in one *focus*.

When both surfaces of a lens are *concave*, or when one is concave and the other plane, the emergent rays will be bent *from* the axis. The mathematical demonstration of these facts, their application to practical purposes, and to the explanation of natural appearances, belong to OPTICS; to which article attention is directed.

11. Some crystallized bodies have the property of dividing the rays of light which permeate them into two distinct portions, one of which passes in the ordinary direction, whilst the other pencil undergoes an extraordinary refraction, passing at some distance from the other. Hence, when any body is viewed through such a crystal in a certain direction, both sets of rays become apparent by giving a double image of the object. This curious property was first detected by Erasmus Bartholin, in calcareous spar brought from Iceland. But the subject was first philosophically investigated with his usual sagacity by Huygens.

Light. who proved that the property of double refraction was not confined to calcareous spar; and it has, since his time, been shown, that all crystals, the primitive form of which is neither a cube nor a regular octahedron, possess this property. Newton attempted to explain this double refraction; but his explanation was not happy. He ascribed it to an original difference in the rays of light, by which some are refracted in the usual manner, whilst others undergo unusual refraction. Huygens discovered, that when the ray of light was received through the Iceland crystal in any direction but one, it was always divided into two rays of equal intensity; but he remarked with surprise, that when he received the divided rays through a second crystal of Iceland spar, the two portions into which each of them was now subdivided were no longer equally intense; that their relative brightness depended on the position of the second rhomb with regard to the first; and that there were two positions of the second, in which one of the rays vanished altogether. This Newton supposed to depend on the rays having different sides, possessed of different properties, each of which "answers to or sympathizes with that virtue or disposition of the crystal, as the poles of two magnets answer to one another."

This idea was followed up by Malus. He conceived that the molecules of this *modified light* have all their homologous sides in the same direction; and he expressed this modification of light by the term *polarization*, as he compared the effect produced to the influence of a magnet, which directs the poles of a series of needles all to the same side; an hypothesis which Biot modified by supposing that each molecule of light had one *axis*, similarly placed in each, and all turned in one direction, in a polarized ray; whilst the molecules were conceived to have a free motion round such axes, by which they could assume different positions according to the attractions and repulsions they experience at the surface of each new medium they traverse. The term *polarization* is not certainly very happy, and it is to be regretted that one more appropriate and less hypothetical had not been employed.

If the rays, thus divided into two pencils by calc spar, be received by a rhomb of the same substance, whilst the axes of both crystals are in the same direction, no new division of the rays takes place; but if, whilst the first crystal remains at rest, the second be turned round, by the time it has made one eighth of a revolution the rays will be again subdivided, and four images will be produced. By continuing the motion until the crystal has described one fourth of a revolution, the subdivision will again disappear.

Malus discovered that an analogous effect was produced by *reflection*. If a pencil of rays fall on a polished surface of glass at an angle of $35^{\circ} 25'$, it is reflected at any angle equal to the angle of incidence. If we now place another plate of glass in such a position that the rays reflected from the first shall fall on the second also at an angle of $35^{\circ} 25'$, or when the plane of both reflections coincide, the rays will also be reflected from the second plate; but if the second plate be turned round one quarter of a revolution, so as to make the plane of the second reflection perpendicular to the plane of the first, the whole of the rays will now be transmitted through the second plate. When this plate has described half a revolution, the rays will be reflected as at first; and when it has made three quarters of a revolution, they will again be transmitted, that is, when the planes of reflection are parallel, light is reflected, but when they are perpendicular, it is transmitted; or light in such circumstances can permeate glass in one direction, but not in another. Sir David Brewster, soon after Malus, began a vast series of experiments to determine the angles of polarization of different media, and to investigate the general law which regulates polarization by reflection from transparent bodies, which was crowned with the beautiful discovery

Light. that "the tangent of the angle of polarization is equal to the refractive index," or that when a ray is entirely polarized by reflection, "the angles of incidence and refraction are complementary." In this sketch it would be impossible to do justice to the investigations and beautiful theoretical deductions of Fresnel, which have combined the whole into an inductive science. We must direct the reader to the article on OPTICS for his important labours, as well as for the profound researches of Airy, Poisson, Biot, Arago, and Cauchy.

Newton rejected the explanation of double refraction offered by Huygens, because he considered the apparent polarization of the rays of light as inconsistent with motions "propagated through a fluid medium;" but this arose from his limiting his ideas of luminous vibrations, as entirely analogous to those of producing sound in air, in which they are propagated in the direction of the advance of the undulations. We owe to the late Dr Thomas Young the first idea of the vibrations being *transverse* to the direction of the luminous wave; an hypothesis which he illustrated by the propagation of the vibrations of a stretched cord put in motion at one of its ends. This happy idea has been shown to be a necessary consequence of the phenomena of the interference of polarized light, if we admit the theory of luminous waves. The subsequent investigations of Arago and of Fresnel have confirmed the speculations of the English philosopher, which have connected and elucidated those brilliant discoveries that have conferred lustre on the names of Malus, Fresnel, and Brewster. See OPTICS.

SECT. IV.—COLOUR OF OBJECTS.

The discovery by Newton of the colours produced by the decomposition of the sun's rays, naturally turned the attention of that profound philosopher to the cause of colour in different objects; and he has delivered a theory of colours, of which we shall now exhibit an outline.

1. Newton regards the colour of natural objects, not as produced by any modification which light undergoes from refraction or reflection at their surfaces, but as something inherent in the rays according to their different degrees of refrangibility. The same degree of refrangibility invariably gives the same colour; and when the rays are fully separated from each other by the prism, he found it impossible to change the colour. Thus he refracted the red ray with prisms, but found its tint unaltered; he reflected it from bodies which in daylight had other colours, but still it remained *red*; he transmitted it through coloured media of different tints, he passed it through the coloured rings produced by pressing together plates of glass, but he was unable to convert it into another colour. By condensation or dispersion he could render it stronger or fainter, but still it remained red. Similar experiments on the other rays were attended with similar results.

2. He found, however, that by mingling the different rays of the coloured spectrum, he could produce a sort of intermediate tint. Thus the intermixture of the yellow and red rays formed an orange, and that of the yellow and blue, a green. But this effect was only distinctly produced by the intermixture of contiguous rays; if they were far removed from each other in the spectrum, no such effect was produced. Thus the orange and indigo rays do not produce an intermediate green.

3. The intermixture of all the rays reproduced white light. Newton reflected a pencil of rays through a prism into a dark room, and then interposing a lens of three feet radius, about four or five feet distance from the aperture admitting the light, he collected the convergent rays upon a paper screen, and obtained an intense spot of white light. By

Light. moving the paper he could easily find the point of perfect whiteness; and, by drawing it farther from the lens, he could reproduce the coloured spectrum in an inverted order, as the crossing rays diverged farther from each other.

If any of the coloured rays were cut off before their convergence by the lens, the image upon the paper exhibited colour; and if either of them were made to predominate, that tint was rendered perceptible. Newton endeavoured to show the same with mixtures of coloured powders; and though this method presents mechanical difficulties not easily overcome, and the mixtures only afford a gray shade, yet when these were strongly illuminated by concentrated solar light, they became of a dazzling white; whilst all coloured objects appeared most splendid in the prismatic rays of their own colour. From these facts he considered the colour of objects to depend upon the predominance of the coloured rays they reflect. Thus minium, or red lead, appears red, because it reflects principally the least refrangible rays; a violet appears of the colour so denominated, because it chiefly reflects the most refrangible rays; and what we denominate the colour of an object is merely the hue of the rays which it most copiously returns to the eye.

On the other hand, transparent bodies which have colour, when held between the eye and the light, appear so by transmitting most copiously that ray. Thus, too, we see why a body not quite transparent may sometimes appear of different colours by transmitted and reflected light. Such a body may transmit most copiously the blue rays, and reflect the green ones; as we often find in coloured liquids, and sometimes observe in the crystals of fluor spar, and other mineral substances. This fact is a confirmation of the Newtonian theory of colour; for, were the *colour* inherent in the substance itself, it ought to appear equally by either mode of viewing it.

In transparent coloured liquids the shade often varies with the thickness of the column through which the light is transmitted. Thus a clear red liquid in a conical wine glass appears below of a pale yellowish hue; higher up it seems orange, and only has its full red hue when the column is of considerable thickness. This is owing to the most refrangible rays never being able to penetrate the liquid at all. The remaining part of these rays gives the yellowish colour to the thin film at the bottom of the glass; the separation of part of the yellow rays gives an orange tint to the next film of liquid; and, when the yellow rays are wholly stopped by the thicker column, the red, or least refrangible, come undiluted to the eye of the observer, and give their colour to the body of the liquid in the glass. See CHROMATICS.

SECT. V.—RELATION OF LIGHT AND HEAT.

It is well known that light and heat are intimately mixed in the beams of the sun; that some bodies give out both light and heat during combustion; and that a high temperature causes the extrication of light in all bodies, the gases excepted. This intimate relation between light and heat has induced some philosophers to consider them as mere modifications of each other. Certain it is that they have many properties in common. They are capable of reflection, of refraction, of concentration, of dispersion, and of polarization; they radiate between distant objects with great celerity, they penetrate solid bodies very readily, they are absorbed by dark and rough surfaces, are generally reflected by smooth surfaces, and they are capable of subverting some chemical combinations.

These properties show very striking analogies; and the phenomena of the polarization of heat, so well illustrated by Professor Forbes of Edinburgh, have undoubtedly rendered this analogy still more apparent: yet in the present state of our knowledge, it would be rash to pronounce that they

are absolutely identical. Their total separation, at least as far as our means of detection extend, in some instances; the very different substances which permit or retard their progress; and the different manner in which they affect our sensations, have led some inquirers to the opposite conclusion; and though it may still be true that they are modifications of the same kind of matter, it is safest to content ourselves with pointing out those circumstances in which they differ, as well as their general agreements.

1. Light and caloric are not intercepted by the same substances. If we interpose a plate of thin transparent glass between the face and a bright blazing fire, the intensity of the light has no apparent diminution, but the caloric rays seem to be immediately arrested; and if we make the experiment with a thin diaphanous plate of ice, they seem absolutely intercepted. Some recent experiments of Professor Forbes, with thin plates of ice, afforded an almost microscopic effect on the galvanometer of Melloni's apparatus; but supposing there was no minute hole in the ice, the difference of the transmission of light and heat through diaphanous ice is sufficiently striking. The same takes place with all other species of terrestrial light, though, as we shall presently see, the caloric rays of the sun instantaneously pervade ice.

2. The rays of caloric are more powerfully reflected from a metallic mirror, even of an imperfect shape, than from the best glass mirror; whereas the latter very powerfully reflects light. Dark and dense solids are very readily penetrated by caloric, though they are totally impervious to light.

3. Light affects the organs of vision in a peculiar manner, without producing inconvenience to that most delicate organ, the eye; but a radiation of heat without light, as from a vessel of boiling fluid, though the rays entering the eye may be so powerful as painfully to affect that organ, does not produce any thing analogous to vision.

In the sun's rays, however, heat and light are so intimately blended, that we cannot entirely separate them. The difference in their refractive power causes a partial separation in the coloured spectrum; but both the heat and light of the sun's rays seem to pervade glass or ice with equal facility. Leslie's photometer, placed behind a sheet of diaphanous ice, is immediately affected by the direct rays of the sun, and a lens of transparent ice will concentrate them, so as to fire combustibles; as was long ago observed by Jan Metius and Descartes, and has more recently been proved by Scoresby. The difference between the caloric influence of the sun and of artificial fires has been attributed to the different initial velocity imparted to the caloric emanations in both cases. This is not improbable; but some have considered the caloric influence of the sun's rays as an effect of the condensation or fixation of light. This was the idea of the late celebrated Sir John Leslie, and is the principle of his elegant *photometer*.

SECT. VI.—MEASURES OF LIGHT.

Various methods have been proposed for affording comparative measures of light. The principles of these depend either on the illumination, as ascertained by the distance at which we can distinctly perceive small objects, such as printed letters of a certain size; the comparative depths of the shadows of an opaque object; or the heat excited by the luminous emanations of the bodies compared.

1. The distance at which the same eye can read a particular printed paper forms certainly a good criterion of the comparative degree of light given out by two or more luminous bodies, at the moment of comparison; but as it must greatly vary with the goodness of eye, it obviously cannot afford the basis of a general scale of illumination,

Light.

Light. by which the same individual can compare his observations at distant periods, or render the experiments of one person comparable with those of another. Still it is a convenient method, and requires but a very simple apparatus; a tube to admit the light in an uniform manner to the paper, and a graduated sliding rule to ascertain with ease the distance of the paper from the eye.

2. The comparison of shadows, which appears first to have been employed by Bouguer amongst several other ingenious contrivances, was the mode recommended by Count Rumford, who, in the year 1794, read a paper on this subject to the Royal Society of London. It is reprinted in a volume of his Philosophical Papers, published in 1802. This instrument, though well suited to the object in view, is cumbersome, and somewhat complicated. The photometric part *a* is a box eight inches wide; its back a plate of glass, covered by tissue paper, on which the shadows are projected. It is supported at a convenient height by a tripod-stand. The table consists of two narrow arms *c d*, resting on *b* at one end, and kept horizontal by feet at the other, intended to support the moveable brackets *e e*, on which are placed the lights to be compared. The arms are divided into decimals of an inch; and are here represented on a smaller scale than the rest of the instrument.

Rumford's Photometer.

Similar results may be obtained by the following contrivance, proposed, we believe, by Dr W. Ritchie. It consists of a rectangular box of brass, *a, b, c, d*, three inches long, and 2.2 inches wide. In its centre are two plane

Light.

Ritchie's Photometer.

glass mirrors, *g g*, two inches square, cut from the same plate, and placed accurately at angles of 45° to the base of the box, as in the diagram. Each end *e f* of the box is open, and has, at equal distances from the mirrors, two cylindrical wires of brass, *h, h*, 0.2 inch in diameter, fixed vertically in the centre of the box. The top of the box consists of two thin plates of glass, *i i*, on which is pasted tissue paper. The inside of the box and the wires are blackened. When the two lights to be compared are placed before the ends of the box, and in its axis, the shadows of the wires will be reflected from the inclined mirrors on the tissue paper. The adjustments of the lights to the machine may be conveniently made by sliding brackets, placed on a long and steady table. If one of the lights be fixed, the other is to be moved backwards or forwards, in the line of the axis of the machine, until both shadows of the wires shall be of equal intensity. Thus, as the intensity of the light, in such cases, is inversely as the square of the distance of the luminous body, the difference between the position of each light, ascertained either by a graduated fillet on the table, or by a common Gunter's scale, will afford a numerical value of the comparative intensity of each light. The method appears sufficiently accurate for such experiments, but, like the former mode, is not susceptible of a fixed scale, unless we could find some uniform unvarying light to be considered as a standard.

Leslie's Photometer.

3. The calorific influence of luminous matter was proposed as the measure of the light by Lambert, and was adopted by Sir John Leslie as the principle on which he constructed his photometer. It is the author's differential thermometer, with one of its balls made of black enamel, whilst the other is of clear glass. An instrument so prepared, when exposed to a heating cause, has its balls unequally heated. To prevent the influence of currents of air, the whole is covered with an air-tight case of transparent glass. The black ball absorbs the calorific rays which impinge on it, the air within it expands, and raises

Light. the coloured liquor in the opposite stem of the instrument, to which a scale of equal parts being attached, each equivalent to $\frac{1}{10}$ th of a degree of the centigrade thermometer, affords a numerical result; and if we were sure that the intensity of the light is always in proportion to the calorific effect, the instrument would be a perfect photometer. But, unfortunately, we now know that this is not the fact, especially when we compare different kinds of light by means of this instrument. Thus the influence of a fire, so dull that it is impossible to distinguish a letter of a printed page, will affect this photometer at the distance of several feet, more than the diffused light of day sufficient to enable one to read the same book with facility; and it is more affected by radiation from a piece of iron scarcely incandescent in the dark, than by the intense light of phosphorus burning in oxygen gas. Even with the light of the sun refracted by the prism, the photometer does not indicate the point of the maximum of light. The greatest illumination is in the yellow rays; but this photometer rises highest when in or just beyond the confines of the red.

But if we employ the instrument for the purpose chiefly in the view of its ingenious inventor, the measure of the intensity of solar light, this beautiful instrument appears to us the most elegant and useful photometer hitherto proposed. Its delicacy is such, that when freely exposed, in our climate, to the light of the sky, without being acted on by the direct solar rays, it generally ranges in summer from 30° to 40° , and in winter from 10° to 15° . Exposed freely to the sun-beams at noon in summer, it usually mounts to between 80° and 90° ; and in the depth of winter is generally about 25° . In the glowing language of its inventor, "the photometer exhibits distinctly the progress of illumination from the morning's dawn to the full vigour of noon, till evening spreads her sober mantle. It marks the growth of light, from the winter solstice to the height of summer, and its subsequent decay through the dusky shades of autumn; and it enables us to compare, with numerical accuracy, the brightness of distant countries—the brilliant sky of Italy, for instance, with the murky air of Holland."

SECT. VII.—EVOLUTION OF LIGHT WITHOUT APPRECIABLE HEAT.

The most familiar instance of this phenomenon is in the rays of the moon, planets, and fixed stars, in the beams of which the most delicate instruments, even the thermomagnetic combinations of Melloni, have been unable to detect any calorific effect. In the beams of the moon and planets, the greatest portion of the incident heat would probably be absorbed by the dark nucleus of those celestial bodies; and if any heating rays were emanated from them towards us, they probably are far too attenuated to produce sensible effects at our planet. The light of the fixed stars, though probably like that of the sun, radiates through too enormous a distance to become sensible to any instrument for measuring heat hitherto contrived. The luminous meteors, too, that belong to our atmosphere, have in general no sensible heat; if we except meteoric stones and condensed electricity or lightning, which has occasionally fired combustibles. We must not confound the effect of the aurora borealis on the magnetic needle with heat; it appears to be altogether magnetic, not calorific. We find, also, that certain terrestrial bodies have the power of emitting light, in some instances largely, without a corresponding degree of heat; and such are usually termed *phosphorescent*. Some of these have the property of absorbing light when exposed to it, and again visibly emitting it. Some become phosphorescent when slightly heat-

Light. ed; others give out light during their spontaneous decomposition. Phosphorescence has been examined by Bartholini, Fabricius ab Aquapendente, Bayle, Algarotti, Reaumur, Father Beccari, Father Bourges, Abbé Haller, Leroi, and Canton.

1. Many bodies, when exposed to light, particularly that of the sun, absorb it, and emit it immediately on being removed into a dark place. When a diamond of some size is thus exposed, it has been observed to give out flashes of light in the dark for a short period, and it recovers this property on a fresh exposure. Several other precious stones, some calcareous minerals, almost all animal and vegetable substances, when very dry, or after solution in nitrous acid, and even snow, are stated by Beccari to possess the same property in a greater or less degree. Several artificial compounds, when carefully calcined, have the same effect. This is particularly the case with the *Bolognian stone*, and with Canton's phosphorus. The former is a calcined sulphate of baryta, found at the foot of Monte Paterno, near Bologna. Its properties were first discovered by Vincenzo Cascariolo, a shoemaker of that city, who, from its weight, mistaking it for a metal, attempted its reduction. The inventor kept the process secret, but it appears to have at length transpired. According to Kircher, the stone was reduced to a fine powder, beaten up with whites of eggs or linseed oil, and formed into a paste, which was repeatedly baked in a furnace. The Bolognian stone, as the preparation was called, has a very powerful phosphorescence, of a reddish colour; and the Italian preparation generally has this quality in a higher degree than the imitations prepared elsewhere; but it has been quite eclipsed by the phosphorus of Canton. Canton recommends oyster shells which have been long worn on a sea-beach, as the materials to be employed. They are to be calcined in a good coal-fire for half an hour. The purest parts are then to be collected, and reduced to a fine powder. Three parts of this, with one of sulphur, are to be rammed into a crucible about $1\frac{1}{2}$ inch deep, till nearly full. Place it in the midst of the fire, where it must be kept red hot for at least one hour, and then allowed to cool, when the contents are to be removed from the crucible. The fine portions of this, which will be quite white, are to be scraped off, and immediately enclosed in a bottle with a well-ground stopple.

When this bottle is exposed for a short time to the light of day, to any artificial light, or, better, to the direct rays of the sun, it will be luminous for some minutes in the dark; and its light will be renewed by a fresh exposure to the sun. At one time it was a subject of controversy, whether or not these substances emitted only the light they had imbibed by exposure, as it was conceived to be a ready mode of deciding the dispute between the followers of Newton and Descartes respecting the nature of light. Galeazzo, Zanotti, and Algarotti of Bologna, tried whether, when exposed to the different rays of the prism, the Bolognian phosphorus would only show the colour of that ray to which it had been exposed; and they thought that its light was reddish, to whichever ray it had been previously exposed. But in these experiments its light was very feeble, and therefore not satisfactory. Afterwards, however, Father Beccari of Turin, by exposing pieces of more powerful phosphori in tubes of different coloured glass, found that, in the dark, they only emitted the colour of the light to which they had been exposed.

Van Helmont appears to have discovered another powerful phosphorus; and Baldwin of Misnia, in 1677, found that the residuum of a solution of chalk in aquafortis, after distillation, formed a phosphorus of considerable power, but inferior to that of the Bolognian. Du Fay, in 1734, found that similar properties resided in gypsum, marble, and topaz. The emerald, diamond, and many other precious

Light. stones, he found to have the same property, without calcination, and by mere exposure to light. From the experiments of Margraaf, all the earthy sulphates have this property when calcined; but he thought that neither metals, metallic ores, nor agates, possess it. The analysis of topaz shows that it contains fluoric acid; and we may now generalize the observation, and state, that all substances capable of becoming phosphorescent by calcination contain some fixed acid, and probably all minerals containing such acids are capable of becoming, in like manner, phosphorescent.

The experiments of Canton are the most complete on this subject (*Phil. Trans.* lviii.). When his phosphorus was, for a short time, exposed to the light of a candle, the moon, or the diffused light of day, it shone for a considerable time in the dark. When exposed to the direct rays of the sun, it gave out light for two hours, at the common temperature of the air. When it had ceased to shine in the dark, the application of heat renewed its luminousness for a short time. If the glass containing the phosphorus be placed in boiling water, its luminousness will be stronger than in the cold, but will last a shorter time. When it has ceased to give light in hot water, it will again give out light on being placed on a hot iron between 400° and 700° Fahrenheit.

2. Some natural bodies become phosphorescent by a gentle heat. Thus, some kinds of fluor spar, particularly the coloured varieties, give out a pure greenish or a bluish light by being heated; and this is finely exhibited by the green varieties. The mineral called *phosphorite*, which is a fibrous phosphate of lime, found principally in Spanish Estremadura, gives out much light when heated. Some marbles, some ores of metals, coal, wax, butter, oil, and several other mineral and vegetable substances, so treated, become more or less luminous. In some the light is momentary, in others it lasts several minutes. It soon attains its maximum brightness, and then fades away. A stream of cooler air extinguishes the light for a moment, but it re-appears on the ceasing of the cool current. Analogous to this class of bodies in some degree are those substances which give out light on percussion; such as siliceous minerals, either with one another or with steel, hard porcelain, or the like; but they also, in such collisions, emit heat as well as light.

3. Mineral and vegetable bodies, during their decomposition, often give out light. Fish, mutton, and rotten wood, are the best known instances of phosphorescent bodies of this class.

The luminousness of fish is well known; and Dr Hulme has shown that the light of herrings and mackerels begins to appear whilst the fish is still eatable, and soon arrives at its maximum, but begins to decrease when they pass to putridity. To produce this change, the fish should be kept in a dark and cool place. It is not confined to the skin of the animal, for if cut into pieces, the surface of each piece becomes luminous; and it is often seen within the mouth of the fish. The luminous matter easily rubs off, and may be transferred to the hands of him who touches the fish. This light is not attended by any perceptible heat. When scraped off, it forms a gelatinous liquid, that will shine for several days, if preserved in a phial. The addition of fresh water, lime water, water impregnated with carbonic acid, of vegetable acids and alkalies, extinguishes it, as do neutral salts, infusions of pepper, and camphor, when strong; yet the same substances, in a weak solution, seem to promote it, and even render it more durable; but sea-water increases its splendour. This luminous property is also found in lobsters and in testacea, especially in the *Pholas Dactylus*, and its congeners. This animal is luminous when quite fresh, and is mentioned by Pliny as rendering the mouths of those who eat it luminous. The light is readily impart-

ed to milk and sea-water, but it is extinguished by spirit, wine, or vinegar. Sea-water, thus rendered luminous, increases in brightness by a gentle heat; but when heated to 133° Fahrenheit, it is suddenly extinguished, and cannot again become luminous. This luminous matter, when narrowly examined, sometimes appears to give out a sort of lambent flame, which closely resembles that of a solution of common phosphorus in oil; and it smells of phosphorus or of phosphuretted hydrogen. The flesh of *Mammalia* undergoes similar changes during its decomposition. This has often been seen in mutton, beef, and veal. This light has sometimes been observed on corpses, much to the terror of the vulgar; and in vaults where dead bodies have been deposited, it has sometimes been observed in a glairy matter adhering to the vault. This last matter, however, probably is the produce of some cryptogamian plant; and it is well known that rotten wood is sometimes highly luminous. A light of this kind is stated to have been observed round the body of a woman at Milan, but it flitted from the bed on the approach of the reporter. This appearance has been more frequently seen around graves, and has obtained in Scotland the name of *elf-candles*.

The light from corrupting animal and vegetable matter requires oxygen in some form for its continuance. It is soon extinguished in the exhausted receiver of the air-pump, as Mr Boyle long ago observed; but it would seem that the small quantity of air which is contained in water is sufficient to sustain its luminousness. No perceptible heat is extricated in any of these kinds of phosphorescence.

Analogous to the light given out by decaying organized bodies, is the curious meteor termed *ignis fatuus*, or *will-o'-the-wisp*. Its ordinary appearance is like the faint flame of a taper; sometimes it resembles the light of a torch, or a faggot; but it usually recedes as it is approached, and can rarely be observed near at hand. The colour of the light is usually pale bluish, and seems brightest when most distant. It is most frequent in marshy grounds, in churchyards, or where a considerable mass of animal and vegetable putrefaction is going on. Dr Derham once observed an *ignis fatuus* playing round the head of a dead thistle; and, by cautiously approaching, he got within two or three yards of it, when a slight movement of the air made it flit; and when he pursued it, he was unable to overtake it.

A remarkable appearance of *ignis fatuus* was, about a century and a half ago, common in the vicinity of Bologna, which has been well described by Beccari (*Phil. Trans.* vii.). He estimated that two, which at that time appeared almost every dark night, one to the east, the other to the north, of the city, gave light equal to an ordinary faggot. One of them accompanied a friend of Beccari for a mile along the road to Bologna, giving as much light as that of the torch carried before him. Sometimes these meteor divided into several parts, or floated like waves of flame, dropping small scintillations.

Dr Shaw, the author of *Travels in the Holy Land*, describes a remarkable one which accompanied him, for upwards of an hour, in one of the valleys of Mount Ephraim. Its shape was at first globular, but it afterwards spread so as to involve the party of the traveller in a pale inoffensive blaze, then disappeared; again it re-assumed the globular form, and again expanded itself, at certain intervals, over more than two or three acres of the adjacent mountains. The atmosphere that evening had been very hazy, and the dew, as it fell on their bridges, felt unusually unctuous and clammy; a kind of weather, says Shaw, in which sailors observe the balls of fire that flit about the masts and yards of ships.

The cause of *ignis fatuus* has been disputed. It can scarcely be accounted for by the phosphorescence of the glow-worm, or any species of fire-fly. It differs also from electric flame, but has the greatest resemblance to the flame

Light. of phosphuretted hydrogen; a gas which spontaneously inflames, on coming into contact with air, and which is given out during the corruption of organic matter. This gas is absorbable by water and by fatty oils, to which last it imparts its phosphorescent qualities; and perhaps the luminousness of fish may depend upon the union of this substance with oily or mucous matter. There is some difficulty in accounting for the appearance so constant and considerable as that described near Bologna. The ground on which the largest meteor appeared is a hard clay, very retentive of water; whilst in the hilly district, where the Bolognian ignis fatuus was smaller, the soil was a loose sand. Becari however states, that they chiefly frequented the banks of streams. All accounts confirm the absence of sensible heat from these meteors.

SECT. VIII.—LIGHT EMANATING FROM LIVING ANIMALS.

A luminous appearance somewhat similar to that given out by decaying organic matter is occasionally observed to play round some classes of living animals; and regularly emanates from the bodies of others, at particular seasons; or as a constant concomitant of motion, by another class.

Of the first kind, probably, is that light sometimes observed playing around the ears and manes of horses, which, though by some attributed to electricity, is probably an emanation from the animal itself; and may perhaps consist of a phosphuretted gas, disengaged by some unknown process of the animal economy. A lambent flame, of a similar nature, has in a few instances been remarked around the heads of children; a circumstance which is happily seized by Virgil in his fine description of the glory that appeared on the temples of the young Ascanius.

Ecce levis summo de vertice visus Iuli
Fundere lumen apex, tractuque innoxia molli
Lambere flamma comas, et circa tempora pasci.
Æn. ii. 683.

Living vegetables, in like manner, also occasionally give out light. This has been particularly noticed in the marigold, the orange, the Indian pink or *lilium bulbosum*, *aconitum napellus*, *tropæolum majus*, and other plants. But there are animals in whom luminousness forms a necessary part of their economy.

The most familiar instance of this is the common glow-worm, *lympyrus noctiluca*, and its congeners. The male of this species is a *coleopterous* insect, and sports in the air; whilst the female is *apterous*, doomed for ever to crawl amongst herbaceous plants, or to nestle on the leaves of shrubs; but when the shades of evening are drawn around, during the summer months, a spot of lucid yellow light, generally tinged with a shade of green, emanates from the extreme rings of her abdomen, and sprinkles the hedges, in some parts of our island, and the warmer parts of Europe, with brilliant stars. The final object of this light is probably to attract the notice of the male insect, who otherwise could with difficulty distinguish his wingless mate. The male of the English glow-worm is generally believed to be destitute of the apparatus for light; though Mr Walker (*Phil. Trans.* for 1684) asserts, that the male of one species of English glow-worm has the luminous appendage. The winged species of glow-worm are common in Italy, Spain, the south of France, and still more so in equinoctial America, in which the flickering light of the numerous fire-flies affords a pleasing and interesting spectacle. This light is found to belong to both sexes, though it is most striking in the females.

But the luminous property of the *Fulgora Lanternaria* of South America surpasses that of all animals, in the splendour of its light. It is a large insect, of the order *Hemip-*

Light. *tera*, three and a half inches long. It has a sort of thick proboscis, about one inch in length, which is the luminous organ. The light emitted by this species is so splendid that two or three of them will illuminate a chamber.

In all these animals the light has so much the appearance of phosphorus dissolved in oil, that probably it may be a secretion of an analogous nature.

Many animals inhabiting the sea are highly luminous; and it is almost established that the luminousness so often exhibited by the ocean depends entirely upon myriads of minute phosphorescent animals.

This appearance is not constant, but is very frequent in most latitudes, and generally, whenever the night is dark, may be seen exceedingly brilliant around our own coasts. When the water is still, it is seen as numerous bright points of a bluish white phosphorescent light of considerable intensity; but when the water is agitated, as by the waves, the motion of a ship, or the dashing of oars, the light appears often in flashes so intense as to show the hours on a watch, or to render legible the pages of a large printed book. The number of the luminous points varies greatly at different times and in different places; and often in the course of a short sail this fluctuation is very conspicuous. We have observed the coruscations, during a gentle breeze, like a line of fire several hundred yards in length from the bows, or in the wake of the vessel. This appearance is found in every sea, but with some difference in intensity and colour, as it seems to proceed from various genera of animals.

The luminousness of the sea was long ascribed to electricity; but about the beginning of this century it was proved, in many instances, to depend on the presence of animalcules in the ocean, particularly of a minute species of medusa, which abounds in our seas, and seems to be the same as *M. Hemisphaerica* of Muller. Several years before, Sir Joseph Banks discovered other two animals which rendered the sea luminous, viz. a sort of shrimp, *Cancer Fulgens*, and a large medusa, *M. Pellucens*, both of which abound on the coasts of Brazil.

From 1810 to 1814, the writer of this article made many observations on this subject, both on the coasts of Britain and in the Bay of Biscay. When the water was very luminous in that sea, on several evenings he drew water and carried it for examination into the cabin. Of course it ceased to appear luminous when viewed by candle light, but he could distinguish, floating in a glass of sea-water, a number of pellucid animalcules, which, when magnified by the globular form of the containing vessel, evidently belonged to several species of *Medusaria*, amongst which he could observe the genera *Noctiluca* of Lamarck, a *Cayanea*, and a *Beroë*. The general size of these animals was from one twentieth to one thirtieth of an inch in diameter. That the luminousness of the sea was derived from these minute animals, appears to be proved by the following simple experiments. Portions of this sea-water were put into separate beer glasses, and the number of animalcules in each was carefully ascertained. They were carried successively to the deck, and when the water was dashed on it, the number of lucid points was ascertained. In most instances the number of these points coincided with the number of animals previously observed in the glass; in no instance were the lucid points *more*; though occasionally they were not so numerous, probably owing to some of them adhering to the glass, or having escaped the shock that stimulated their light-making organs. The same animals he has often observed, even more numerous, in the luminous sea-water of the British coasts; and has obtained similar results by a repetition of the experiments. The luminous points often adhere to the fingers; and on introducing such a luminous speck into a glass of non-luminous sea-water, careful inspection will show a medusary animal

Light. floating in the water. The sea-water, on such occasions, if left at rest in glass vessels on deck, or even if suspended in gimbals, would occasionally exhibit luminous points; and the author conceives that the light either attends the voluntary movements of those minute creatures, or is emitted at their will. When sulphuric or other strong acid is poured into luminous water, it will produce a considerable flash of light, either by the effort of the animals to escape, or the unexpected stimulus it produces. In some climates the sea exhibits a fiery-red hue. This has often been observed in the Chinese seas, and in some parts of the Indian Ocean. It is produced, according to the best authorities, by myriads of minute animals that emit a reddish light. Captain Horsburgh and Mr Langstaff have described other kinds of light occasionally observed in the Indian Ocean. The latter mentions, that during a passage from China to New Holland, the sea at night had a faint milky appearance, as if snow had just fallen on the water. The sailors thought it was produced by a coral shoal, but seventy fathoms of line did not find bottom; and when the water drawn up was examined, it was observed to swarm with minute globular bodies, about the size of a pin's head, linked together, and of a milky hue, probably some minute species of medusa. It is well known that the larger fish are sometimes luminous. This has been remarked in the bonito and the shark; but whether they are naturally luminous, or only in consequence of the adhesion of luminous animalcules to them, is not determined.

Some have ascribed the luminousness of the sea to electricity, others to putrescent particles in the water. The former opinion is not probable, from the appearances observed; the latter is supported by the luminous matter of dead fish being diffusible through water, and imparting to it luminous qualities; but the known phosphorescence of many small sea animals, and the coincidence of the number of scintillations, in the experiments above detailed, with that of the animals observed, incline us to believe that the luminous appearance of the ocean depends on the presence of minute animals.

SECT. IX.—CHEMICAL EFFECTS OF LIGHT.

Light appears to be possessed of chemical properties and energies distinct from those of heat, which may be considered as further proofs of its materiality.

It is capable of decomposing various metallic salts. Thus, if a colourless solution of nitrate of silver be exposed to light, it gradually blackens; a powder is deposited which has the same colour, and the salt is found to have lost a portion of its oxygen. This change is more rapidly effected by the direct rays of the sun than by the diffused light of day. The neutral solutions of gold, also, when exposed to light, in contact with charcoal, with vegetable or animal matter, as cotton and silk, are decomposed. This is the principle of the beautiful process invented by Mrs Fulham, for ornamenting muslin and silk stuffs with flowers and sprigs of gold. The salt of gold parts with its acid and its oxygen to the vegetable or animal matter through the agency of light. The dry salt formed by dissolving gold in nitro-muriatic acid is also slowly decomposed by light under similar circumstances.

Scheele examined the effects of light on metallic solutions, and discovered that the chemical effects of the different coloured rays of the prismatic spectrum were different. By enclosing solutions of silver in glasses of different colours, he found, that in red glass there was very little effect produced, whilst in violet-coloured glass the blackening was speedily produced. These interesting facts were confirmed by Senebier and by Thomas Wedgwood.

Light. The latter showed, that in the full sunshine, the blackening of muriate of silver was produced in two minutes, and in the shade that several hours were required to produce this effect. The sunbeams transmitted through red glass have very little blackening effect; yellow and green glass are somewhat more effectual; but blue and violet glass produce the most decisive effects. The discovery of Herschel, respecting the different refrangibility of light and heat, induced Ritter and Wollaston to try the effect upon the salts of silver beyond the violet ray; and they found that the blackening was most decided beyond the visible boundary of the spectrum at the violet end. In some experiments of Senebier, muriate of silver was darkened by the violet ray in 15", by the blue in 29", by the green in 37", by the yellow in 5' 30", by the orange in 12', and by the red in 20'. These effects are wholly due to light; for no effect is produced in the hottest point just beyond the red rays.

Berthollet proved, that during the action of light on many metallic oxides, as those of gold, silver, lead, and mercury, a portion of their oxygen was extricated; and this is supposed to be the change produced in the blackening of the salts of silver, viz. a partial reduction of the metal. Sir Humphry Davy found that tritoxide of lead, when moistened, and exposed to the red rays, became red, that is, it lost oxygen, and became a deutoxide. Oxide of mercury, obtained by mixing potash and calomel, was not changed by the most refrangible rays, but became red in the least refrangible rays, which must have resulted from the *absorption* of oxygen. The violet rays produced on the moistened red oxide of mercury the same effect as a stream of hydrogen gas, that is, a deoxidation. Wollaston found that these rays produced an *oxidizing* effect on one vegetable substance, resin of guaiacum. This resin becomes green by absorbing oxygen; and he found that it underwent this change in the violet rays, but again obtained its yellow hue on being exposed to the red rays.

Some of the acids suffer decomposition by light; thus, if we expose colourless nitric acid to the sun's rays, in a flask provided with a bent tube, and terminating in a pneumatic apparatus, the acid becomes coloured, from the formation of nitrous gas, and oxygen may be collected in the trough in the usual way, as Berthollet ascertained. Light also decomposes some vegetable acids, such as the hydrocyanic; and to preserve such compounds pure, it is necessary carefully to exclude light.

Light also in some cases favours chemical combination. If chlorine which has been collected over water, and therefore contains water, be exposed to light, the water is slowly decomposed; its hydrogen enters into combination with the chlorine to form hydro-chloric or muriatic acid, and its oxygen is liberated. The influence of light is still more striking on chlorine and on hydrogen. If we mix equal proportions of these gases, and the access of light be carefully excluded, no action takes place, or their union is very slowly produced; but if we expose them to the diffused light of day, combination will take place in a quarter of an hour. If exposed to the direct beams of the sun, the union is instantaneous, and with a violent explosion. Davy found that when such a mixture was exposed to the red rays only, the gases united without explosion, yet more rapidly than when exposed to the violet rays; but that the conversion of a solution of chlorine into muriatic acid took place most readily at the most refrangible end of the solar spectrum.

SECT. X.—EFFECTS OF LIGHT ON PLANTS.

The change produced on vegetable colouring matter by light is familiar in the process of bleaching by exposure to

Light. the sun. But the influence of light on living vegetables is much more remarkable.

If a plant grow in total darkness, its natural green hue is not acquired; but it will be white, though in other respects vigorous. This is familiar in the *etiolation* or blanching of certain garden-stuffs, as celery, sea-kale, endive, &c. The late Professor Robison, many years ago, remarked that plants growing in darkness were not only white, but that they did not attain the natural form of their leaves, nor their natural odour. In descending into a coal mine, he accidentally met with a plant growing luxuriantly, the form and qualities of which were entirely new to him. The sod on which it grew was removed, potted, and carefully attended to in his garden. The etiolated plant languished and died; but the roots speedily threw out vigorous shoots, which, from the form of the leaves, and peculiar odour, he readily recognised as common *tansy*. He repeated similar experiments upon plants of lovage, carvi, and mint, with analogous results.

The green colour of vegetables, and even the form of their leaves, are materially influenced by light.

Some experiments of Senebier would lead to the conclusion that it is the violet end of the spectrum which has the greatest influence in counteracting the effects of *etiolation*. This production of the dark colour of plants would appear to depend upon the decomposition of carbonic acid by the living vegetable, when acted on by light, and the fixation of its carbon. That light is necessary to this process, is proved by the experiments of Priestley, Senebier, Ingenhousz, De Saussure, Davy, and many vegetable physiologists. Growing plants in sunshine give out oxygen by the decomposition of carbonic acid; but in darkness carbonic acid is evolved; and Ellis has demonstrated, in his interesting essays, that oxygen, under such circumstances, always disappears from the air in which vegetation is going on. Light, then, acts an important part in the vegetable economy, by fixing the most dense and abundant of the three general elements of vegetable matter. The influence of light in maturing fruits is well known. The fruits which when ripe are saccharine, are previously *acid*; that is, their hydrogen and carbon are combined with an excess of oxygen. Light, by favouring the evolution of oxygen, and the fixation of carbon, converts the vegetable acid into sugar, and thus provides a suitable food for the embryo in the seed. On the other hand, the influence of light is not less conspicuous in another class of vegetables. In an early stage of the germination of seeds yielding farina when ripe, the tender rudiment of the seed is enveloped in a slightly saccharine juice, as may be seen in young wheat and maize. Now, what is wanted to convert them into farina is the evolution of oxygen, and the fixation of a larger quantity of carbon. These two indications are fulfilled by the influence of light on the growing vegetables; and thus we can explain why the sun's influence is so essential in the one case to the formation of sugar from an acid; and in the other, of farina from a saccharine juice. The same principles will explain why a farinaceous seed, when planted in the ground, becomes again saccharine. Light is now wanting; oxygen is absorbed, and partly aids in the evolution of the redundant carbon, partly is added to the two other general elements. This view affords an instance of the important agency of light in vegetation, and a beautiful example of the simplicity of the means employed to produce diversified effects in the works of creation.

SECT. XI.—EFFECTS OF LIGHT ON ANIMALS.

The facts noticed in the last section show the powerful influence of light on vegetable forms. But its effects on

the exterior of animals, though less striking, are not unimportant.

Light.

1. The influence of the sun's rays in deepening the colour, or in giving a brown tint to the skin, seems to be more due to the light than to the heat of the sunbeams; for the parts of the skin covered by the clothes, though kept thus hotter than the parts exposed, do not undergo this change. The pale visage and enfeebled vitality of those who live much in obscure apartments, in prisons, and in mines, are well known; and though probably the most violent symptoms that characterize the *anhæmia* of miners, in which the skin assumes a yellowish, waxy hue, and the lips become bloodless, be chiefly due to breathing a vitiated atmosphere, yet some influence is certainly attributable to want of light. The *anhæmia* of persons long confined in dungeons has often been remarked, and was lately described as strikingly exemplified in the person of Caspar Hauser, the young man whose mysterious birth, confinement, and assassination, have hitherto baffled conjecture.

In climates where the heat renders a state almost approaching to nudity desirable, all travellers agree that the development of the human frame is early, and the form has fewer deviations from the symmetry natural to the race than amongst northern nations. Deformity is said to be comparatively rare in hot climates, where the surface is much exposed; and this has been attributed by Dr Edwards in some measure to the influence of light. Perhaps, after making due allowance for the less chance of rearing sickly or deformed children amongst barbarous nations, and for the prevalence of infanticide amongst them in such cases, there is considerable justice in his remarks on this subject; without which it would be difficult to account for the fine muscular and rounded forms so often observed amongst nations agreeing in nothing except in the prevalence of a very free exposure of their persons to the full influence of light; as amongst the Mexicans and Peruvians, the Chaymas and Muyscas of South America, the Caribbs of the Antilles, the inhabitants of the numerous groups of the South Seas, or the free inhabitants of Africa. Probably, too, a part of the effects attributed to country air, in restoring to health the sickly child of the city artizan, is due to *insolation*, or the exposure to light, which appears to have the property of invigorating the vital functions, and of elevating the spirits of those who have suffered a long deprivation of its cheering influence.

2. The effect of light on the lower animals is more marked, and is strikingly illustrated in the curious experiments of Dr W. F. Edwards upon the spawn of frogs. He enclosed portions of the spawn of the frog in different vessels permeable to water, some of which were perfectly opaque, while others freely admitted light; the temperature was the same, yet the eggs exposed to light came to maturity; but those deprived of light were not hatched.

He even found that the development of the perfect form of such animals depended on light. By enclosing tadpoles of both frogs and toads in different boxes, some of which freely admitted light, whilst others totally excluded it, and placing them in running water, he found that the tadpoles exposed to light underwent the change to the perfect form of the animal, as usual; whilst the tadpoles excluded from the light, though they seemed perfectly vigorous, did not undergo the transformation, even though they had increased to double or triple their primitive weight. He also conjectures that the Anguine Syren, *Proteus anguinus*, may only be the larva of some reptile retained in its imperfect form by the profound obscurity of the subterranean lakes of Carniola, in which it is found. In this conjecture, however, he is mistaken; for that singular animal has been kept alive without change a considerable time, under circumstances favourable to its transformation, if really an imperfect species,

Light. by various naturalists; particularly, as we have been informed, by the Austrian archduke John; and also by the late Mr Melly, a zealous naturalist once resident in Liverpool.

The facts, however, already detailed, show that the influence of light on the animal economy is by no means inconsiderable. But the most interesting property of light, in relation to animals, is its effect in producing vision.

3. The rays of light emanating from bodies, or reflected from their surfaces, are destined to impress the sensorium through the EYE; an admirable and complex optical apparatus, in which the rays, after passing through the transparent *cornea*, *a*, sustain various refractions, until they reach the sentient expansion of the optic nerve, *f*, called *retina*. The cornea constitutes the front of the eyeball, the rest of its surface is formed of a dense white tunic, called the *sclerotic coat*, *bb*, which joins the cornea by its edges, forming with the latter an almost globular body, which contains the more delicate structures of the eye. Just within the cornea is observed a coloured ring, apparently formed of diverging fibres, termed the *iris*, *hh*. This ring is perforated by the *pupil*, a circular aperture in its centre, which is capable of contraction and expansion, by the action of the fibres of the iris, according to the increase or diminution of the light. This movement of the pupil is not under the will of the animal, but is regulated by the stimulus of light, so as to exclude any quantity that would be hurtful to the organ. The iris is attached to the outer coat of the eye, the sclerotic, by the *ciliary processes*, *nn*. Within the sclerotic lies a delicately thin vascular membrane named the *choroid coat*, having its interior surface lined with a black secretion termed the *pigmentum nigrum*, the probable use of which is to aid clear vision, by preventing a multiplicity of reflections in the bottom of the eye.

Still nearer to the centre of the eye lies the *retina*, which is continuous with the optic nerve, *f*, and is the part of the eye sentient to the impressions of light. Entering the bottom of the eye, but not just in its axis, is seen a thick cord, the *optic nerve*, by which the impressions upon the retina are conveyed to the brain.

The bulk of the eyeball is made up of three substances, which have been improperly termed *humours*. The first lies just within the cornea, and fills the space between it and the iris, as well as the smaller space immediately behind the latter. From its fluidity, it is termed the *aqueous humour*, *g*. The iris divides the chamber of the aqueous humour into an *anterior* and a *posterior portion*. The posterior wall of this chamber is formed by a delicate, transparent, capsular membrane, enclosing a lenticular body, convex on both sides, though more so posteriorly, which is named the *crystalline lens*, *l*. This body consists of concentric layers, formed of fibres externally less consistent, but increasing in density towards its centre; a structure intended for the purpose of correcting its *spherical aberration*. The capsule of the crystalline lens is retained in its situation by the *ciliary circle* or *ciliary processes*, *n*; and it lies imbedded in the most considerable of all the humours of the eye, the *vitreous*, *m*, which consists of a clear gelatinous substance, that recent anatomical investigations prove to be lodged in very delicate membranous cells. In the healthy state, especially in young persons, these humours are perfectly colourless and transparent, but they become coloured by age; and the crystalline lens has been seen in very old persons of a bright amber colour, though still transparent. Opacity of the lens forms the disease termed *cataract*. The obvious use of the humours of the eye is to refract the rays of light entering the eye by the transparent *cornea*, and to concentrate them on the *retina*. The difference in their consistence seems intended to make that organ a true and nicely adjusted achromatic optical instrument.

The ray from any object falling directly in the centre of the eye, perpendicular to its surface, will not undergo any refraction, but pass straight through to the retina; and its direction may be termed the *axis of the eye*. All the rays which fall obliquely on the eye will, by the refraction of the humours, be bent from their course, and cut the axis somewhere between the lens and the retina; and the refractive power of the humours is such as to converge on the retina all rays proceeding from any one point of a visible object, whether these rays fall on the cornea in a parallel or a diverging condition. But as these rays have all crossed the axis of the eye by the refractive power of the humours, it is obvious that the rays from the upper part of the object will impinge on the lower part of the retina, and those from the lowest point, on the upper part of that membrane. Hence the image of the object will be *inverted* on the retina. That this actually takes place we can easily satisfy ourselves, by removing from the posterior part of the eye of a sheep a portion of the sclerotic coat with a sharp knife, until it becomes translucent, when the image of a candle placed before the cornea will be seen inverted on the back part of the eye thus prepared.

In the usual state of the eye, its refractive apparatus is so contrived that all the rays from the same points of objects at some distance from the eye will *converge in the retina*, or the *principal focus of the eye will lie in that membrane*; but divergent rays from very near objects would converge in a point *behind the retina*, were there not some power of adjustment in the eye for correcting the confused image which would thus be formed. This may be effected in two ways; either by increasing the convexity of the cornea, or by bringing the lens to a greater distance from the retina. Some have attributed this adjustment to an alteration in the form of the eyeball, and consequently of the cornea, by the action of the motor muscles of the organ; but there is much more probability in the opinion that this adjustment is produced by the contractions and expansions of the *iris*. This part

Light.

Light.

of the eye is attached to the ciliary ligament, which is also connected with the capsule of the crystalline lens. Hence contraction of the pupil would tend to draw forward the lens, or remove it farther from the retina; and thus the rays which have their point of convergence *behind* the retina, would meet in that membrane, and a distinct image would be produced. That some such adjustment is necessary is obvious; for if, after contemplating a distant object, our attention be suddenly turned to a very near one, it is some time ere the second object is distinctly perceived; and the movement of the iris will be seen to take place before the second image is well defined. The retina is capable of affording the perception of external objects in its whole extent, except at the insertion of the optic nerve, a spot about $\frac{1}{10}$ th of an inch in diameter in man. Any image falling on this spot is invisible, as multiplied experiments have shown. This insensible point in either eye may be indicated by the familiar optical experiment of placing three coloured wafers horizontally on a wall, on a white ground, about two feet from each other. Let the operator place himself about two feet from the wall, opposite the middle wafer; shut one eye, and then gradually retire backwards, while he fixes his open eye on the wafer nearest the closed eye. When an ordinary eye is distant from the wall about *five times* the distance of the wafers from each other, the image of the middle wafer will have fallen on the insertion of the optic nerve, and will no longer be visible.

Two very interesting speculations connected with vision have long exercised the ingenuity of physiologists and metaphysicians, viz. how it happens that animals with two eyes see objects *single*, by means of double images on the retina; and how they appear *erect* by means of inverted images?

The first has been explained on the supposition of there being corresponding points in each eye that convey similar perceptions to the mind, and that such afford only the idea of *unity*. In the natural movements of the eyes, the images of external objects are supposed always to fall on such points; but should any cause throw the images on dissimilar points, then we have double vision. Hence, if with the finger we push one eyeball slightly out of its parallel position with regard to the other, two objects are perceived. In persons who squint, the parallel movement of the eyes is lost; and it has been supposed that in cases where the squinting has come on in adults from imperfection in one eye, that habit enables the individual to correct the illusion of double vision, and that the person ceases to notice the impressions made on the least perfect of the two eyes.

The second fact alluded to is that of *erect* vision by *inverted* images. That images of external objects are depicted inverted on the retina is perfectly well ascertained; and philosophers have been much puzzled to explain how the indications of vision and touch are reconciled. Some have imagined that at first we really see objects inverted, but learn by experience and by the sense of touch to correct the illusion. Other attempts have been made to explain it by what has been termed the *law of visible direction*; by which it is supposed that when any point of an object is viewed, the rays proceeding from that point must fall on the eye with different degrees of obliquity, yet that point will be only seen in the direction of the central ray of the cone of light proceeding from that point: And as the lines of *visible direction* must necessarily cross each other at the centre of visible direction, those of the lower part of the image on the retina must go to the upper part of the object, and those of the upper part of the image to the lower part of the object; and hence an erect object is considered as the necessary result of an inverted image.

This is very ingenious, but it is obviously hypothetical

and obscure. The physiological explication of single vision by double images suggested by Newton, and since supported by Wollaston, is based on what has been termed the *semi-decussation* of the optic nerves at their commissure, whereby the right half of the retina of each eye is placed in direct nervous communication with the right optic lobe, or right half of that part of the brain termed *corpora quadrigemina*, and *vice versa*. Hence impressions made on corresponding points in each retina may, in fact, be impressions on the *same points of the common sensorium*, and therefore co-operate in producing the same perception. The anatomical proof of this is still defective, but many facts give it probability. The subject has engaged the attention of Professor Alison of Edinburgh, who considers that this arrangement of the optic nerves is but a part of the provision by which nature has secured harmony between perceptions afforded by sight and touch. His explanation of one of the most perplexing questions in animal physiology is so ingenious, that we gladly avail ourselves of his permission to lay it before our readers.

According to him, the peculiar contorted or involuted course of the optic nerves (in all vertebrate animals) around the crura cerebri, until they are lost in the optic lobes, seems designed to secure that the position of the *impression on the sensorium* should be conformable to the true position of the object.

It is only in those animals intended by nature to contemplate objects with both eyes at once, as in mammalia and birds, that the semi-decussation of the optic nerve is found. The contrivance in fact implies that both eyes are to be at the same time directed to the same object, or that both optic lobes are to be constantly employed in vision at the same time; the right half of each retina being in connection with each optic lobe, and the left half of each retina in like manner connected with the left optic lobe. Now, the *right* half of each retina contains the image of the *left* half of the field of vision; and therefore the impressions made by the left half of the field of vision fall on the right optic lobe, and have, on their left, the impression resulting from the right side of the field of vision; on which, as both optic lobes are necessarily exercised together, the attention of the mind is equally directed.

Dr Alison considers that the grand contrivance adopted by nature to secure harmony between the indications of sight and touch is the *decussation at the pyramids* of the nervous fibres concerned in common sensation and in voluntary movements; the effect of which must be, that whilst the right side of the brain is that to which impressions from the left half of the field of vision are brought, it is also *that* on which all the other sensations of the left side of the body depend; or, in other words, *we both see and feel what is on our left by the right side of the brain*. Accordingly, it is in those animals only in which the semi-decussation of the optic nerves exists (namely, in *Mammalia* and birds) that the decussation at the pyramids exists, or that the sensations and voluntary motions of each side of the body appear to be in connection with the opposite side of the brain.

As the admirable mechanism of the eye, and its beautiful adaptation to the necessities and comfort of the animal creation, afford a striking instance of that wisdom and beneficence so conspicuous in the handiwork of the Deity; so the extinction of this exquisite and important organ must be considered as one of the severest of human calamities; a misfortune that perhaps cannot be fully appreciated by those who have not experienced the loss of sight, so feelingly deplored by our mighty bard in poetry that can only perish with the language in which it is expressed.

Thus with the year
Seasons return, but not to me returns

Light.

Light-
houses.

Day, or the sweet approach of even or morn,
Or sight of vernal bloom or summer's rose,
Or flocks, or herds, or human face divine;
But cloud instead, and ever during dark
Surrounds me, from the cheerful ways of men
Cut off, and for the book of knowledge fair
Presented with an universal blank
Of nature's works, to me expunged and raz'd,
And wisdom at one entrance quite shut out.

Light-
houses.

LIGHTHOUSES.

LIGHTHOUSE, and sea-light, are terms which, although not strictly synonymous, are indifferently employed to denote the same thing. A *Sea-light* may be defined as *a light so modified and directed as to present to the mariner an appearance which shall at once enable him to judge of his position during the night, in the same manner as the sight of a landmark would do during the day.*

Early his-
tory.

The early history of lighthouses is very uncertain; and many ingenious antiquaries, finding the want of authentic records, have endeavoured to supply the deficiency by conjectures founded on casual and obscure allusions in ancient writers, and have invented many vague and unsatisfactory hypotheses on the subject, drawn from the heathen mythology. Some writers have gone so far as to imagine, that the Cyclopes were the keepers of lighthouses; whilst others have actually maintained that Cyclops was intended, by a bold prosopopœia, to represent a lighthouse itself. A notion so fanciful deserves little consideration; and in order to show how ill it accords with that mythology of which it is intended to be an exposition, it seems enough to quote the lines from the ninth *Odyssey*, where Homer, after describing the darkness of the night, informs us that the fleet of Ulysses actually struck the shore of the Cyclopean island before it could be seen.

"Ενθ' ὕπναις πῆν νῆσον ἐσέβρακεν ὀφθαλμοῖσιν
"Οὐτ' οὖν κύματα μακρὰ κυλινδόμενα ποτὶ χέρσον
"Εἰσίδομεν πρὶν νῆας εὐσείλους ἰστυίλσαι.

Odys. ix. 146.

There does not appear any better reason for supposing, that under the history of Tithonus, Chiron, or any other personage of antiquity, the idea of a lighthouse was conveyed; for such suppositions, however reconcileable they may appear with some parts of the mythology, involve obvious inconsistencies with others. Nor does it seem at all probable, that in those early times, when navigation was so little practised, the advantages of beacon-lights were so generally known and acknowledged as to render them the objects of mythological allegory.

Colossus of
Rhodes.

About 300 years before the Christian era, Chares, the disciple of Lysippus, constructed the celebrated brazen statue, called the Colossus of Rhodes, whose height was upwards of 100 feet, and which stood at the entrance to the harbour. There is considerable probability in the idea, that this figure served the purposes of a lighthouse; but we do not remember any passage in ancient writers,

where this use of the Colossus is expressly mentioned. There is much inconsistency in the account of this fabric by early writers, who, in describing the distant objects which could be seen from it, appear to have forgotten the height which they assign to the figure. It was partly demolished by an earthquake, about 80 years after its completion; and so late as the year 672 of our era, the brass of which it was composed was sold by the Saracens to a Jewish merchant of Edessa, for a sum, it is said, equal to L.36,000.

Little is known with certainty regarding the Pharos of Alexandria, which was regarded by the ancients as one of the seven wonders of the world. It was built by Ptolemy Philadelphus, about 300 years before Christ; and it is recorded by Strabo, that the architect Sostratus, the son of Dexiphanes, having first secretly cut his own name on the solid walls of the building, covered the words with plaster, and, in obedience to Ptolemy's command, made the following inscription on the plaster—"King Ptolemy to the gods, the saviours, for the benefit of sailors." What truth there may be in this account of the fraud of Sostratus there is now no means of determining; and the story is only now interesting, in so far as it shows the object of the royal founder and the use of the tower. The accounts which have reached us of the dimensions of this remarkable edifice are exceedingly various; and many of the statements regarding the distance at which it could be seen are clearly fabulous. Josephus approaches nearest to probability, and informs us, that the fire which was kept constantly burning in the top was visible by seamen at a distance equal to about 40 miles. If the reports of some writers are to be believed, this tower must have far exceeded in size the great pyramid itself; but the fact that a building of comparatively so late a date should have so completely disappeared, whilst the pyramid remains almost unchanged, is a sufficient reason for rejecting, as erroneous, the dimensions which have been assigned by most writers to the Pharos of Alexandria. Some have pretended that large mirrors were employed to direct the rays of the beacon-light on its top, in the most advantageous direction; but there is nothing like respectable evidence in favour of this supposition. Others, with greater probability, have imagined that this celebrated beacon was known to mariners, simply by the uncertain and rude light afforded by a common fire. In speaking of the Pharos,¹ the poet Lucan, on most occasions

¹ Septima nox, Zephyro nunquam laxante rudentes,
Ostendit Phariis Ægyptia littora flammis.
Sed prius orta dies nocturnam lampada textit,
Quam tutas intraret aquas.

Light-houses.

sufficiently fond of the marvellous, takes no notice of the gigantic mirrors which it is said to have contained. It is true that, by using the word "*lampada*," which can only with propriety be applied to a more perfect mode of illumination than an open fire, he appears to indicate that the "*flammæ*" of which he speaks were not so produced. The word *lampada* may, however, be used metaphorically; and *flammis* would, in this case, not improperly describe the irregular appearance of a common fire. Those who are desirous of knowing all that occurs in ancient authors on the subject of the Pharos of Alexandria may consult Pliny, l. xxxvi., c. 12.; l. v., c. 13., and l. xiii., c. 11. Strabo, l. xviii., p. 791, *et seq.* Cæsar, *Comment. de Bell. Civil.*, l. iii. Pompon. Mela, l. ii., c. 7. Ammian. Marcellin, l. xxii., c. 16. Joseph. *de Bell. Judaic.*, l. vi. Nicolas Lloyd's *Lexicon Geographicum*, and the *Notitia Orbis Antiqui* of Celarius, l. iv., c. 1., p. 13.

Coruna Tower.

Mr Moore, in his *History of Ireland* (vol. i., p. 16), speaks of the Tower of Coruña, which, he says, is mentioned in the traditionary history of that country as a lighthouse erected for the use of the Irish in their frequent early intercourse with Spain. In confirmation of this opinion, he cites a somewhat obscure passage from Æthicus, the cosmographer. This in all probability is the tower which Humboldt mentions in his Narrative under the name of the *Iron Tower*, which was built as a lighthouse by Caius Sævius Lupus, an architect of the city of Aqua Flavia, the modern Chaves. A lighthouse has lately been established on this headland, for which dioptric apparatus was supplied from the workshop of M. Létourneau of Paris. (See also a curious account of the traditions about this tower in Southey's *Letters from Spain and Portugal*, p. 17.)

There is also a record in Strabo of a magnificent lighthouse of stone at Capio, or Apio, near the Harbour of Menestheus (the modern Mesa Asta, or Puerto de Sta. Maria), built on a rock nearly surrounded by the sea, as a guide for the shallows at the mouth of the Guadalquivir, which he describes in terms almost identical with those used by him in speaking of the Pharos of Alexandria. I am not aware of any other notice of this great work, for such it seems to have been, to have deserved the praises of Strabo.¹

In Camden's *Britannia*, a passing notice is taken of the ruins called *Cæsar's Altar*, at Dover, and of the *Tour d'Ordre*, at Boulogne, on the opposite coast; both of which are conjectured, on somewhat doubtful grounds, to have been ancient lighthouses. Pennant describes the remains of a Roman Pharos near Holywell, but cites no authorities for his opinion as to its use. There were likewise remains of a similar structure at Flamborough-head. A very meagre and unintelligible account is also given of a lighthouse at St Edmund's Chapel, on the coast of Norfolk, in Gough's additions to Camden, by which it might seem that the lighthouse was erected in 1272.²

Modern history.

Such seems to be the sum of our knowledge of the ancient history of lighthouses, which, it must be admitted, is neither accurate nor extensive. Our information regarding modern lighthouses is of course more minute in its details, and more worthy of credit, as the greater part of it is drawn from authentic sources, or is the result of the actual observation of the writer of this article, who has visited the most important lighthouses of Europe. It seems sufficient here to notice briefly the most remarkable establishments of the kind now in existence; reserving, for the latter part of the article, the more appropriate and important topics of the methods of illumination, and the systems of management.

Tour de Corduan.

The first lighthouse of modern days which merits attention is the Tour de Corduan, which, in point of architec-

tural grandeur, is unquestionably the noblest edifice of the kind in the world. It is situate on an extensive reef at

Light-houses.

Fig. 1.

the mouth of the River Garonne, and serves as a guide to the shipping of Bordeaux and the Languedoc Canal, and, indeed, of all that part of the Bay of Biscay. It was founded in the year 1584, and was not completed till 1610, under Henri IV. It is minutely described in Belidor's *Architecture Hydraulique*. The building is 197 feet in height, and is shown in the accompanying woodcut, fig. 1. Round the base is a wall of circumvallation, 134 feet in diameter, in which the light-keepers' apartments are formed, somewhat in the style of casemates. The first light exhibited in the Tour de Corduan was obtained by burning billets of oak-wood, in a chauffer at the top of the tower; and the use of coal instead of wood was the first improvement which the light received. A rude reflector, in the form of an inverted cone, was afterwards added, to prevent the loss of light which escaped upwards. About the year 1780, M. Lenoir was employed to substitute reflectors and lamps; and in 1822 the light received its last improvement, by the introduction of the dioptric instruments of M. Fresnel.

The history of the celebrated lighthouse on the Eddy- Eddystone stone rocks is well known to the general reader, from the narrative of Mr Smeaton the engineer. These rocks are 9½ miles from the Ram-Head, on the coast of Cornwall; and from the small extent of the surface of the chief rock, and its exposed situation, the construction of the lighthouse was a work of very great difficulty. The first erection was of timber, designed by Mr Winstanley, and was commenced

¹ Oxon, 1807, p. 184.

² Gough's Camden's *Britannia*, vol. i., 318, and vol. ii., p. 198. Batcheller, in his *Dover Guide* (1845, p. 111), says, that the Dover Pharos was built "during the lieutenancy of Aulus Plautius and Ostorius Scapula, the latter of whom left Britain A.D. 53" (Pennant's *History of Whiteford and Holywell*, p. 112).

Light-
houses.

in 1696. The light was exhibited in November 1698. It was soon found, however, that the sea rose upon this tower to a much greater height than had been anticipated, so much so, it is said, as to "*bury under the water*" the lantern, which was 60 feet above the rock; and Mr Winstanley was therefore afterwards under the necessity of enlarging the tower, and carrying it to the height of 120 feet. In November 1703, some considerable repairs were required, and Mr Winstanley, accompanied by his workmen, went to the lighthouse to attend to their execution; but the storm of the 26th of that month carried away the whole erection, when the engineer and all his assistants unhappily perished.

The want of a light on the Eddystone soon led to a fatal accident; for, not long after the destruction of Mr Winstanley's lighthouse, the Winchelsea man-of-war was wrecked on the Eddystone rocks, and most of her crew were lost. Three years, however, elapsed after this melancholy proof of the necessity of a light before the Trinity House of London could obtain a new act to extend their powers; and it was not till the month of July 1706 that the construction of a new lighthouse was begun, under the direction of Mr John Rudyerd of London. On the 28th of July 1708 the new light was first shown, and continued to be regularly exhibited till the year 1755, when the whole fabric was destroyed by accidental fire, after standing 47 years. But for this circumstance, it is impossible to tell how long the lighthouse might, with occasional repair, have lasted, as Mr Rudyerd seems to have executed his task with much judgment, carefully rejecting all architectural decoration, as unsuitable for such a situation, and directing his attention to the formation of a tower which should offer the least resistance to the waves. The height of the tower, which was of a circular form, and constructed of timber, was, including the lantern, 92 feet, and the diameter at the base, which was a little above the level of high water, was 23.

The advantages of a light on the Eddystone having been so long known and acknowledged by seamen, no time was permitted to elapse before active measures were taken for its restoration; and Mr Smeaton, to whom application was

Fig. 2.

made for advice on the subject, recommended the exclusive use of stone as the material, which, both from its weight

Light-
houses.

and other qualities, he considered most suitable for the situation. On the 5th of April 1756, Mr Smeaton first landed on the rock, and made arrangements for erecting a lighthouse of stone, and preparing the foundations, by cutting the surface of the rock into regular horizontal benches, into which the stones were carefully dovetailed or notched. The first stone was laid on 12th June 1757, and the last on the 24th of August 1759. The tower measures 68 feet in height, and 26 feet in diameter at the level of the first entire course, and the diameter under the cornice is 15 feet. The first 12 feet of the tower form a solid mass of masonry, and the stones are united by means of stone joggles, dovetailed joints, and oak treenails. It is remarkable that Mr Smeaton should have adopted an arched form for the floors of his building; instead of employing these floors as tie-walls formed of dovetailed stones. To counteract the injurious tendency of the outward thrust of these arched floors, Mr Smeaton had recourse to the ingenious expedient of laying, in circular trenches or beds in the stones which form the outside casing, sets of chains, which were heated by means of an application of hot lead, and became tight in cooling. The light was exhibited on the 16th October 1759; but such was the state of the lightroom apparatus in Britain at this period, that a feeble light from tallow candles was all that decorated this noble structure. In 1807, when the property of this lighthouse again came into the hands of the Trinity House, on the expiry of a long lease, Argand burners, and parabolic reflectors of silvered copper, were substituted for the chandelier of candles. Fig. 2 shows a section of the Eddystone lighthouse, as executed according to Mr Smeaton's design.

The dangerous reef called the Inch Cape, or Bell-Rock, Bell-Rock. so long a terror to mariners, was well known to the earliest navigators of Scotland. Its dangers were so generally acknowledged, that the Abbots of Aberbrothick, from which the rock is distant about 12 miles, caused a float to be fixed upon the rock, with a bell attached to it, which, being swung by the motion of the waves, served by its tolling to warn the mariner of his approach to the reef. Amongst the many losses which occurred on the Bell-Rock in modern times, one of the most remarkable is that of the York, 74, with all her crew, part of the wreck having been afterwards found on the rock, and part having come ashore on the neighbouring coast. During the survey of the rock also, many instances were discovered of the extent of loss which this reef had occasioned, and many articles of ships' furnishings were picked up on it, as well as various coins, a bayonet, a silver shoe-buckle, and many other small objects. Impressed with the great importance of some guide for the Bell-Rock, Captain Brodie, R.N., set a small subscription on foot, and erected a beacon of spars on the rock, which, however, was soon destroyed by the sea. He afterwards constructed a second beacon, which soon shared the same fate. It was not, however, until 1802, when the Commissioners of Northern Lights brought a bill into parliament for power to erect a lighthouse on it, that any efficient measures were contemplated for the protection of seamen from this rock, which, being covered at every spring-tide to the depth of 12 feet, and lying right in the fairway to the Firths of Forth and Tay, had been the occasion of much loss both of property and life. In 1806 the bill passed into a law, and various ingenious plans were suggested for overcoming the difficulties which were apprehended, in erecting a lighthouse on a rock 12 miles from land, and covered to the depth of 12 feet by the tide. But the suggestion of Mr Robert Stevenson, the engineer to the Lighthouse Board, after being submitted to the late Mr Rennie, was at length adopted; and it was determined to construct a tower of masonry, on the principle of the Eddystone. On the 17th of August 1807, Mr Stevenson accordingly landed with his workmen, and commenced the work by preparing

Light-
houses.

the rock to receive the supports of a temporary wooden pyramid, on which a barrack-house, for the reception of the workmen, was to be placed; and during this operation much hazard was often incurred in transporting the men from the rock, which was only dry for a few hours at spring-tides, to the vessel which lay moored off it. The lowest floor of this temporary erection, in which the mortar for the building was prepared, was often broken up and removed by the force of the sea. The foundation having been excavated, the first stone was laid on the 10th July 1808, at the depth of 16 feet below the high-water of spring-tides, and at the end of the second season, the building was 5 feet 6 inches above the lowest part of the foundation. The third season's operations terminated by finishing the solid part of the structure, which is 30 feet in height; and the whole of the masonry was completed in October 1810. The light was first exhibited to the public on the night of the 1st of February 1811. The difficulties and hazards of this work were chiefly caused by the short time during which the rock was accessible between the ebbing and flowing tides; and amongst the many eventful incidents which rendered the history of this work interesting, was the narrow escape which the engineer and thirty-one persons made from being drowned, by the rising of the tide upon the rock, before a boat came to their assistance, the attending vessel having broken adrift. This circumstance occurred before the barrack-house was erected, and is narrated by Mr Stevenson in his account of the work, published at the expense of the Lighthouse Board in 1824, to which we may refer for more minute information on the subject of this work, and the other lights of the coast of Scotland.

Fig. 3.

The Bell-Rock Tower is 100 feet in height, 42 feet in

diameter at the base, and 15 at the top. The door is 30 feet from the base, and the ascent is by a massive copper ladder. The apartments, including the light-room, are six in number. The light is a revolving red and white light, and is produced by the revolution of a frame containing 20 Argand lamps, placed in the foci of parabolic mirrors, arranged on a quadrangular frame, whose alternate faces have shades of red glass placed before the reflectors, so that a red and white light is shown successively. The machinery, which causes the revolution of the frame containing the lamps, is also applied to tolling two large bells, to give warning to the mariner of his approach to the rock in foggy weather. Fig. 3 shows a section of the Bell-Rock Lighthouse, and of the temporary barrack-house, which was removed on the completion of the work. The entire cost of the lighthouse was L.61,331, 9s. 2d.

The great merit of Mr Stevenson, as architect of the Bell-Rock Lighthouse, lies in his bold conception and unshaken belief in the possibility of erecting a tower of masonry on a reef 12 miles from the nearest land, and covered by every tide,—a situation, undoubtedly, much more difficult than that of the Eddystone. But his mechanical skill in carrying on the work is also deserving of high praise. Not only did he conceive the plan of the *moveable jib* and *balance cranes*, which he afterwards used with much advantage in building the tower; but his zeal, ever alive to the possibility of improving on the conceptions of his great master Smeaton, led him to introduce several beneficial changes into the arrangements of the masonry. In particular, he converted the stone floors of the apartments, which in the Eddystone exert an *outward*, and in its tendency disruptive, thrust, into bonds of union and efficient sources of stability. This thrust was by Smeaton himself considered so disadvantageous, that he thought fit to counteract it, as already noticed, by means of metallic *girders*, concealed in the stone-work, and most ingeniously applied. The Lighthouse Board placed in the upper apartment of the tower a bust of Mr Stevenson, “in testimony,” as the minutes record, “of the sense entertained by the Commissioners of his distinguished talent and indefatigable zeal in the erection of the Lighthouse.”

The most remarkable lighthouse on the coast of Ireland Carlingford is that of Carlingford, near Cranfield Point, at the entrance ford of Carlingford Lough. It was built according to the design of Mr George Halpin, the Inspector of the Irish Lights; and was a work of an arduous nature, being founded twelve feet below the level of high-water on the Hawlbowl Rock, which lies about two miles off Cranfield Point. The figure is that of a frustum of a cone, 111 feet in height, and 48 feet in diameter at the base. The light, which is fixed, is from oil burned in Argand lamps placed in the foci of parabolic mirrors. It was first exhibited on the night of the 20th December 1830.

The Skerryvore Rocks, which lie about 12 miles W.S.W. of the seaward point of the Isle of Tyree, in Argyllshire, were long known as a terror to mariners, owing to the numerous shipwrecks, fatal alike to the vessels and the crews, which had occurred in their neighbourhood. A list, confessedly incomplete, enumerates thirty vessels lost in the forty years preceding 1844; but how many others, which during that period had been reported as “foundered at sea,” or as to whose fate not even an opinion has been hazarded, may have been wrecked on this dangerous reef, which lies so much in the track of the shipping of Liverpool and the Clyde, it would be vain to conjecture.¹ The Commissioners of the Northern Lighthouses had for many years entertained the project of erecting a lighthouse on the Skerry-

Light-
houses.

¹ The islanders of Tyree made regular trips after storms to the Rock, and often returned with their boats loaded with *wreck*. Even during the progress of the works, a ship's anchor, and some chain cable much rusted, and other articles, were fished from the hollows of the reef.

Light-houses. vore; and with this object had visited it, more especially in the year 1814, in company with Sir Walter Scott, who, in

through which the sea plays almost incessantly. The cutting of the foundation for the tower in this irregular flinty mass occupied nearly two summers; and the blasting of the rock, in so narrow a space, without any shelter from the risk of flying splinters, was attended with much hazard.

Light-houses.

Fig. 4.

his diary, gives a graphic description of its inhospitable aspect. The great difficulty of landing on the rock, which is worn smooth by the continual beat of Atlantic waves, which rise with undiminished power from the deep water near it, held out no cheering prospect; and it was not until the year 1834, when a minute survey of the reef was ordered by the Board, that the idea of commencing this formidable work was seriously embraced.

The reef is composed of numerous rocks, stretching over a surface of nearly 8 miles from W.S.W. to E.N.E. The main *nucleus*, which alone presents sufficient surface for the base of a lighthouse, is nearly 3 miles from the seaward end of the cluster. It is composed of a very compact *gneiss*, worn smooth as glass by the incessant play of the waters, and is so small that at high-water little remains around the base of the tower but a narrow band of a few feet in width, and some rugged humps of rock, separated by gullies,

In such a situation as that of Skerryvore everything was to be provided beforehand and transported from a distance; and the omission in the list of wants of even a little clay for the *tamping* of the mine-holes might for a time have entirely stopped the works. Barracks were to be built at the workyard in the neighbouring Island of Tyree, and also in the Isle of Mull, where the granite for the tower was quarried. Piers were also built in Mull and Tyree for the shipment and landing of materials; and at the latter place a harbour or basin, with a reservoir and sluices for scouring the entrance, were formed for the accommodation of the small vessel which attends the lighthouse. It was, besides, found necessary, in order to expedite the transport of the building materials from Tyree and Mull to Skerryvore Rock, to build a steam-tug, which also served, in the early stages of the work, as a floating barrack for the workmen. In that branch of the service she ran many risks, while she lay moored off the rock in a perilous anchorage, with *two-thirds* of the horizon of *foul ground*, and a rocky and deceitful bottom, on which the anchor often *tripped*.

The operations at Skerryvore were commenced in the summer of 1838, by placing on the rock a wooden barrack, similar to that first used by Mr Robert Stevenson at the Bell-Rock. (See Fig. 3.) The framework was erected in the course of the season on a part of the rock as far removed as possible from the proposed foundation of the lighthouse tower; but in the great gale which occurred on the night of the 3d of November following, it was entirely destroyed and swept from the rock, nothing remaining to point out its site but a few broken and twisted iron stanchions, and attached to one of them a piece of a beam, so *shaken* and rent by dashing against the rock as literally to resemble a bunch of laths. Thus did one night obliterate the traces of a season's toil, and blast the hopes which the workmen fondly cherished of a stable dwelling on the rock, and of refuge from the miseries of sea-sickness, which the experience of the season had taught many of them to dread more than death itself. After the removal of the roughest part of the foundation of the tower had been nearly completed, during almost two entire seasons, by the party of men who lived on board the vessel while she lay moored off the rock, a second and successful attempt was made to place another barrack of the same description, but strengthened by a few additional iron ties, and a centre post, in a part of the rock less exposed to the breach of the heaviest waves than the site of the first barrack had been. This second house braved the storm for several years after the works were finished, when it was taken down and removed from the rock, to prevent any injury from its sudden destruction by the waves. "Perched 40 feet above the wave-beaten rock, in this singular abode," says Mr Alan Stevenson, the engineer, "with a goodly company of thirty men, I have spent many a weary day and night at those times when the sea prevented any one going down to the rock, anxiously looking for supplies from the shore, and earnestly longing for a change of weather favourable to the recommencement of the works. For miles around nothing could be seen but white foaming breakers, and nothing heard but howling winds and lashing waves. At such seasons much of our time was spent in bed; for there alone we had effectual shelter from the winds and the spray, which searched every cranny in the walls of the barrack. Our slumbers, too, were at times fearfully interrupted by the sudden pouring of the sea over the roof, the rocking of the house on its pillars, and the spurting of water

Light-houses.

through the seams of the doors and windows—symptoms which, to one suddenly aroused from sound sleep, recalled the appalling fate of the former barrack, which had been engulfed in the foam not twenty yards from our dwelling, and for a moment seemed to summon us to a similar fate. On two occasions, in particular,” says the engineer, “those sensations were so vivid as to cause almost every one to spring out of bed; and some of the men fled from the barrack, by a temporary gangway, to the more stable but less comfortable shelter afforded by the bare wall of the lighthouse tower, then unfinished, where they spent the remainder of the night in the darkness and the cold.”

The design for the Skerryvore Lighthouse was given by Mr Alan Stevenson, and is an adaptation of Smeaton's Eddystone Tower to the peculiar situation and the circumstances of the case at the Skerryvore, with such modifications in the general arrangements and dimensions of the building as the enlarged views of the importance of lighthouses which prevail in the present day seemed to call for.

The tower is 138 feet 6 inches high, and 42 feet in diameter at the base, and 16 feet at the top. It contains a mass of stone-work of about 58,580 cubic feet, or more than double that of the Bell-Rock, and not much less than five times that of the Eddystone. The lower part of the tower was built by means of *jib-cranes*, and the upper part with *shear-poles*, *needles*, and a balance-crane. The shear-poles were similar to those used by Smeaton at the Eddystone; and the *jib-cranes* and *balance-crane* were the same as those which were designed and first employed by Mr Robert Stevenson in the erection of the Bell-Rock Lighthouse. The mortar used was compounded of equal parts of limestone (from the Halkin Mountain, near Holywell, in North Wales), burnt and ground at the works, and of Pozzolano earth. The light of Skerryvore is revolving, and reaches its brightest state *once every minute*. It is produced by the revolution of eight great annular lenses around a central lamp with four wicks, and belongs to the first order of dioptric lights in the system of Fresnel. The light may be seen from a vessel's deck at the distance of 18 miles. The entire cost of the lighthouse, including the purchase of the steam-vessel, and the building of the harbour at Hynish for the reception of the small vessel, which now attends the lighthouse, was L.86,977, 17s. 7d.

“In such a situation as the Skerryvore,” says the engineer, “innumerable delays and disappointments were to be expected by those engaged in the work; and the entire loss of the fruit of the first season's labour in the course of a few hours was a good lesson in the school of patience, and of trust in something better than an arm of flesh. During our progress, also, cranes and other materials were swept away by the waves; vessels were driven by sudden gales to seek shelter at a distance from the rocky shores of Mull and Tyree; and the workmen were left on the rock desponding and idle, and destitute of many of the comforts with which a more roomy and sheltered dwelling, and the neighbourhood of friends, are generally connected. Daily risks were run in landing on the rock in a heavy surf, in blasting the splintery gneiss, or by the falling of heavy bodies from the tower on the narrow space below, to which so many persons were necessarily confined. Yet had we not any loss of either life or limb; and although our labours were prolonged from dawn to night, and our provisions were chiefly salt, the health of the people, with the exception of a few slight cases of dysentery, was generally good throughout the six successive summers of our sojourn on the rock. The close of the work was welcomed with thankfulness by all engaged in it; and our remarkable preservation was viewed, even by many of the most thoughtless, as, in a peculiar manner, the gracious work of Him by whom ‘the very hairs of our heads are all numbered.’”

There can be little doubt that, down to a very late period, the only mode of illumination adopted in the lighthouses, even of the most civilized nations of Europe, was the combustion of wood or coal in a chauffer on the top of a high tower. It is needless to enlarge upon the evils of such a method; they need only be named to be understood; for it is difficult to conceive how an efficient system of lighting a coast could be managed under such disadvantages. The uncertainty caused by the effects of wind and rain, and the impossibility of rendering one light distinguishable from another, must have at all times rendered the early lighthouses in a great measure useless to the mariner.

Light-houses.

Method of illumination.
Coal lights

M. Teulère, a member of the Royal Corps of Engineers of Bridges and Roads in France, is, by some, considered the first who hinted at the advantages of parabolic reflectors; and he is said, in a memoir dated the 26th June 1783, to have proposed their combination with Argand lamps, ranged on a revolving frame, for the Corduan lighthouse. Whatever foundation there may be for the claim of M. Teulère, certain it is, that this plan was actually carried into effect at Corduan under the directions of the Chevalier Borda, and to him is generally awarded the merit of having conceived the idea of applying parabolic mirrors to lighthouses. These were prodigious steps in the improvement of lighthouses, as not only the power of the lights was thus greatly increased, but the introduction of a revolving frame proved a valuable source of distinction amongst lights, and has since been the means of greatly extending their utility. The exact date of the change on the light of the Corduan is not known; but as it was made by Lenoir, the same young artist to whom Borda, about the year 1780, intrusted the construction of his reflecting circle, it has been conjectured by some that the improvement was made about the same time. If this conjecture be correct, the claim of M. Teulère must of course fall to the ground. The reflectors were formed of sheet copper, plated with silver, and had a double ordinate of 31 French inches. It was not long before these improvements were adopted in England by the Trinity House of London, who sent a deputation to France to inquire into their nature. In Scotland, one of the first acts of the Northern Lights Board, in 1786, was to substitute reflectors in the room of coal lights, then in use at the Isle of May in the Firth of Forth, and the Cumbrae Isle in the Firth of Clyde, which had, till that period, been the only beacons on the Scotch coast. The reflectors employed were formed of facets of mirror glass, placed in hollow parabolical moulds of plaster, according to the designs of the late Mr Thomas Smith, the engineer of the Board, who, as appears from the article *Reflector* in the Supplement to the third edition of the Encyclopædia Britannica, was not aware of what had been done in France, and had, himself, conceived the idea of this combination. The system of Borda was also adopted in Ireland; and, in time, variously modified, it became general wherever lighthouses were known.

The property of the parabola, by which all lines incident on its surface from the focus make with normals to the curve at the points of incidence, angles equal to the inclination of these same normals respectively to lines drawn parallel to the axis of the curve, is that which fits it for the purposes of a lighthouse. A hollow mirror, formed by the revolution of a portion of a parabola about its axis, has, in consequence of this property, the power of projecting the repeated images of a luminous point placed in its focus, in directions parallel to the axis of the generating curve; so that, when the mirror is placed with its axis parallel to the horizon, a cylindric beam of light is thereby sent forward in a horizontal direction. When such mirrors are placed side by side, with their axes parallel on the faces of a quadrangular frame which revolves about a vertical axis, a distant observer receives the successive impressions which result from the pas-

Catoptric system.

Parabolic mirrors.

Light-houses.

sage of each face of the frame, over a line drawn between the observer's eye and the centre of the revolving frame. This arrangement constitutes what is called a revolving light. A fixed light is produced by placing, side by side, round a circular frame, a number of reflectors, with their axes inclined to each other, so as to be radii containing equal arcs of the frame on which they are placed. It is obvious that a perfect parabolic figure, and a luminous *point* mathematically true, would render the illumination of the whole horizon by means of a fixed light *impossible*; and it is only from the aberration caused by the size of the flame which is substituted for the point, that we are enabled to render even revolving lights practically useful. But for this aberration, even the slowest revolution in a revolving light, which would be consistent with a continued observable series, such as the practical seaman could follow, would render the flashes of a revolving light greatly too transient for any useful purpose; whilst fixed lights, being visible in the azimuths only in which the mirrors are placed, would, over the greater part of the distant horizon, be altogether invisible. The size of the flame, therefore, which is placed in the focus of a parabolic mirror, when taken in connection with the form of the mirror itself, leads to those important modifications in the paths of the rays, and the form of the resultant beam of light, which have rendered the catoptric system of lights so great a benefit to the benighted seaman.

It is obvious, from a consideration of the nature of the action which takes place in this combination of the paraboloidal mirrors with Argand lamps, that the revolving light is not only more perfect in its nature than the fixed light, but that it possesses the advantage of being susceptible of an increase of its power, by increasing the number of reflectors, which have their axes parallel to each other, so as to concentrate the effect of several mirrors in one direction. The perfect parallelism of the axes of separate mirrors, it is true, is unattainable, but approaches may be made sufficiently near for practical results; and in order to prolong the duration of the flash, the reflectors are sometimes placed on a frame, having each of its sides slightly convex, by which arrangement the outer reflectors of each face of the frame have their axes less inclined inwards from the radii of the revolving frame which pass through their foci.

The best proportions for the paraboloidal mirrors depend upon the object to which they are to be applied; as mirrors which are intended to produce great divergence in the form of the resultant beam should have one form; whilst those which are designed to cause a near approach to parallelism of the rays will have another form. These objects may also be attained by variations of the size of the flame applied in the same mirror; but it is much more advantageous to produce the effect by a change in the form of the mirror, as any increase of the flame beyond the size which is found to be most advantageous in other respects cannot be regarded otherwise than as a wasteful expenditure of light. The details into which a full investigation of this matter would lead us are quite beyond the scope of this article, and it therefore seems sufficient to give the formulæ which express the relations which exist between the size of the flame, the reflecting surface, and the corresponding divergence of the reflected ray. If Δ represent the inclination of any reflected ray to the axis of a paraboloidal mirror, e the distance of the focus from the point of reflection, and d the distance from the edge of the flame to the focus in

the plane of reflection, we shall have $\sin \Delta = \frac{d}{e}$; and when

the flame in the given plane of reflection is circular, or has its opposite sides equidistant from the focus of the mirror, we shall, by putting Δ' for the effective divergence of the mirror in the given plane, have $\Delta' = 2\Delta$. When, there-

fore, great divergence, as in the case of the fixed lights, is required, the prolate form of the curve is to be preferred; and the oblate is conversely more suited to revolving lights.

The power of the reflectors ordinarily employed in light-houses is generally equal to about 360 times the effect of the unassisted flame which is placed in the focus. This value, however, is strictly applicable only at the distances at which the observations have been made, as the proportional value of the reflected beam must necessarily vary with the distance of the observer, agreeably to some law dependent upon the unequal distribution of the light in the luminous cone which proceeds from it. The ordinary burners used in lighthouses are one inch in diameter, and the focal distance generally adopted is four inches, so that the effective divergence of the mirror in the horizontal plane may be estimated at about $14^{\circ} 22'$. In arranging reflectors on the frame of a fixed light, however, it would be advisable to calculate upon less effective divergence, for beyond 11° the light is feeble; but the difficulty of placing many mirrors on one frame, and the great expense of oil required for so many lamps, have generally led to the adoption of the first valuation of the divergence.

The reflectors used in the best lighthouses are made of sheet copper plated, in the proportion of 6 oz. of silver to 16 oz. of copper. They are moulded to the paraboloidal form by a delicate and laborious process of beating with mallets and hammers, of various forms and materials, and are frequently tested during the operation by the application of a carefully-formed mould. After being brought to the curve, they are stiffened by means of a strong beazle, and a strap of brass, which is attached to it for the purpose of preventing any accidental alteration of its figure. Polishing powders are then applied, and the instrument receives its last finish.

Two gauges of brass are applied to test the form of the reflector. One is for the back, and is used by the workmen during the process of hammering, and the other is applied to the concave face as a test, while the mirror is receiving its final polish. It is then tested, by trying a burner in the focus, and measuring the intensity of the light at various points of the reflected conical beam. Another test may also be applied successively to various points in the surface, by masking the rest of the mirror. Having placed a screen in the line of the axis of the mirror at some given distance from it, it is easy to find whether the image of a very small object placed in the conjugate focus, which is due to the distance of the screen, be reflected at any distance from that point on the centre of the screen through which the prolongation of the axis of the mirror would pass, and thus to obtain a measure of the error of the instrument. For this purpose it is necessary to find the position of the conjugate focus, which corresponds to the distance of the screen. If b be the distance which the object should be removed outwards from the principal focus of the mirror, d the distance from the focus to the screen, and r the distance from the focus to the point of the mirror which is

to be tested, we shall have $b = \frac{r^2}{d}$ as the distance which the

object must be removed outwards from the true focus on the line of the axis.

The flame generally used in reflectors is from an Argand fountain-lamp, whose wick is an inch in diameter. Much care is bestowed upon the manufacture of these lamps for the Northern Lighthouses, which have their burners tipped with silver, to prevent wasting by the great heat which is evolved. These burners are also fitted with a slide apparatus, accurately formed, by which the burner may be removed from the interior of the mirror at the time of cleaning it, and returned exactly to the same place, and locked

Light-houses.

Power of paraboloidal mirrors.

Manufacture and testing of reflectors.

Proportions and divergence of paraboloidal mirrors.

Light-houses.

by means of a key. This arrangement, which is shown in figs. 5, 6, and 7, is very important, as it ensures the burner always being in the focus, and does not require the reflector to be lifted out of its place every time it is cleaned; so that, when once carefully set and screwed down to the frame, it is never altered. In these figs. *aaa* represents one of the reflectors, *b* is the lamp, *c* is a cylindric fountain, which contains 24 oz. of oil. The oil-pipe and fountain of the former is connected with the rectangular frame *d*, and is moveable in a vertical direction upon the guide-rods *e* and *f*, by which it can be let down and taken out of the reflector by simply turning the handle *g*, as will be more fully understood by examining fig. 6. An aperture of an elliptical form, measuring about 2 inches by three, is cut in the upper and lower part of the reflector, the lower serving for the free egress and ingress of the lamp, and the upper, to which the copper tube *h* is attached, serving for ventilation; *i* shows a cross section of the main bar of the chandelier or frame, on which the reflectors are ranged, each being made to rest on knobs of brass, one of which is seen at *h*, and which are soldered on the brass band *l*, that clasps the exterior of the reflector. Fig. 5 is a section of the reflector *aa*, showing the position of the burner *b*, with the glass chimney *b'*; and oil-cup *l*, which receives any oil that may drop from the lamp. Fig. 6 shows the apparatus for moving the lamp up and down, so as to remove it from the reflector at the time of cleaning it. In the diagram, *c*, the fountain, is moved partly down; *dd'* shows the rectangular frame on which the burner is mounted, *e, e* the elongated socket-guides, *f* the rectangular guide-rod, connected with the perforated sockets on which the checking-handle *g* slides.

Arrangement of reflectors on the frame.

The modes of arranging the reflectors in the frames are shown in figs. 8, 9, and 10. It seems quite unnecessary, after what is said on the subject of divergence, to do more than remark, that in revolving lights the reflectors are placed with their axes parallel to each other, so as to concentrate their power in one direction; whilst in fixed lights it is necessary, in order to effect as equal a distribution of the light over the horizon, as possible, to place the reflectors, with their axes inclined to each other at an angle somewhat less than that of the divergence of the reflected cone. For this purpose a brass gauge, composed of two long arms, somewhat in the form of a pair of common dividers, connected by means of a graduated limb, is employed. The arms having been first placed at the angle, which is supplemental to that of the inclination of the axes of the two adjacent mirrors, are made to span the faces of the reflectors, one of which is moved about till its edges are in close contact with the flat surface of one of the arms

of the gauge. The different arrangements of the reflectors will be more fully understood by referring to the figures.

Light-houses.

Figs. 8 and 10 show an elevation and plan of a revolving apparatus on the catoptric principle. In these figures, *nn*, shows the reflector frame or chandelier; *o, o*, the reflectors with their oil-fountains *p, p*. The whole is attached to the revolving axis or shaft *q*. The copper tubes, *r, r*, convey the smoke from the lamps; *s, s* are cross bars which support the shaft at *tt*; *uu* is a copper pan for receiving any moisture which may accidentally enter at the central ventilator in the roof of the light-room; *l* is a cast-iron bracket, which supports the pivot on the shaft; *m, m* are bevelled wheels, which convey motion from the machine to the shaft. Fig. 9 shows a plan of one tier of reflectors arranged in the manner employed in a fixed catoptric light; *nn* shows the chandelier, *q* the fixed shaft in the

centre, which supports the whole, *o, o* the reflectors, and *p, p* the fountains of their lamps.

A variety of the parabolic reflectors has been invented by M. Bordier Marcet, the pupil and successor of Argand, who has laboured with much enthusiasm in perfecting catoptric instruments, more especially with a view to their application to the illumination of lighthouses and the streets of towns. Amongst many other ingenious combinations of parabolic mirrors, he has invented and constructed an apparatus, which is much used in harbour-lights on the French coast. The object of this apparatus is to fulfil, as economically as possible, the conditions required in a fixed light, by illuminating, with perfect equality, every part of the horizon, by means of a single burner; and M. Bordier

Bordier Marcet's reflectors.

Light-houses.

Marcet has in his workshop an instrument of this kind, 8 feet in diameter, which he constructed on speculation. The apparatus used in harbour-lights, on the French coast, is of much smaller dimensions, and does not exceed 15 inches in diameter. A perfect idea of the construction and effect of this apparatus may be formed by conceiving a parabola to revolve about its parameter as an axis, so that its upper and lower limbs would become the generating lines of two surfaces possessing the property of reflecting, in lines parallel to the axis of the parabola, all the rays incident upon them, from a light placed in the point where the parameter and axis of the generating parabola intersect each other. This point being the focus of each parabolic section of this apparatus, the light is equally dispersed in every point of the horizon, when the axes of the parabolic sections are in a plane perpendicular to a vertical line. But, however perfectly this apparatus may attain this important object, it does so at the sacrifice of the most efficient part of the parabolic surface, which lies between the vertex and the parameter; and therefore produces a proportionally feeble effect. This beautiful little instrument is shown in fig. 11, in which *b* shows the burner, *pp*

Fig. 10

Fig. 11.

the upper reflecting surface, and *p'p'* the lower reflecting surface, both generated in the manner above described, by the revolution of a parabola, about its parameter *ab*; *F* is the focus of the generating parabola; and *l, l* are small pillars which connect the two reflecting plates, and give strength to the apparatus.

Spherical mirrors.

Spherical mirrors are employed in lighthouses only as subsidiary parts in dioptric apparatus; and any observations regarding them will, therefore, be made in treating of the dioptric lights of Fresnel.

Floating lights.

Floating lights are only resorted to in cases of absolute necessity, as their maintenance is extremely expensive, whilst they are less to be relied on, and, in all respects, less efficient than land lights. They are large vessels, built with great breadth of beam, and are generally moored off shoals, or serve as guides for taking channels. The lights are from lamps placed in front of small reflectors, ranged in lanterns which are hoisted on the masts of the vessel.

Catoptric lights are susceptible of nine separate distinctions, which are called *fixed, revolving white, revolving red and white, revolving red with two whites, revolving white with two reds, flashing, intermittent, double fixed lights, and double revolving lights*. The first exhibits a steady and uniform appearance, which is not subject to any change; and the reflectors used for it are of smaller dimensions than those employed in revolving lights. This is necessary, in order to permit them to be ranged round the circular frame, with their axes inclined at such an angle as shall enable them to illuminate every point of the horizon. The revolving light is produced by the revolution of a frame with three or four sides, having reflectors of a large size grouped on each side, with their axes parallel; and as the revolution exhibits a light gradually increasing to *full strength*, and in the same gradual manner decreasing to total darkness, its appearance is extremely well marked. The succession of *red and white* lights is caused by the revolution of a frame whose different sides present red and white lights; and these, as already mentioned, afford three separate distinctions, namely, alternate red and white; the succession of two white lights after one red; and the succession of two red lights after one white light. The *flashing* light is produced in the same manner as the *revolving* light; but owing to a different construction of the frame, and the greater quickness of the revolution, a totally different and very striking effect is produced. The brightest and darkest periods being but momentary, this light is characterized by a rapid succession of bright flashes, from which it gets its name. The *intermittent* light is distinguished by bursting suddenly into view, and continuing steady for a short time, after which it is suddenly eclipsed for half a minute. Its striking appearance is produced by the perpendicular motion of circular shades in front of the reflectors, by which the light is alternately hid and displayed. This distinction, as well as that called the *flashing light*, are peculiar to the Scotch coast, having been first introduced by Mr R. Stevenson, the late engineer of the Northern Lights Board. The double lights, which are generally used only where there is a necessity for a *leading* line, as a guide for taking some channel, or avoiding some danger, are exhibited from two towers, one of which is higher than the other; and when seen in one line, form a direction for the course of shipping. At the Calf of Man a striking variety has been introduced into the character of leading lights, by substituting for two *fixed* lights, two lights which revolve in the same periods, and exhibit their flashes at the same instant; and these lights are, of course, susceptible of the other variety enumerated above, that of two revolving red and white lights revolving in equal periods. The utility of all these distinctions is chiefly to be imputed to their at once striking the eye of an observer, and being instantaneously obvious to strangers.

Light-houses.

Before entering upon the subject of the dioptric lights,¹ Dioptric the writer of this article embraces with pleasure the opportunity afforded to him of acknowledging the liberality of M. Fresnel. Léonor Fresnel, the late Secretary of the Lighthouse Commission of France. It was entirely owing to the readiness with which M. Fresnel afforded him access to every avenue of information on the subject of lighthouses that he was enabled to effect the object of a mission to France, on which he was sent in the year 1834, by the Commissioners of Northern Lights.

The first proposal of applying lenses to lighthouses is recorded by Smeaton in his account of the Eddystone Lighthouse, where he mentions that, in 1759, an optician in London proposed grinding the glass of the lantern to a

¹ In all probability directly derived from the Greek *διόπτρον*, an optical instrument with holes for looking through, which is a compound of *διὰ*, through, and *σκοπεῖν*, I see.

Light-houses.

radius of seven feet six inches; but the description is too vague to admit of even a conjecture regarding the proposed arrangement of the apparatus. About forty years ago, however, lenses were actually tried in several light-houses in the south of England; but their imperfect figure, and the quantity of light absorbed by the glass, which was of inferior quality and of considerable thickness, rendered their effect so much inferior to that of the parabolic reflectors then in use, that, after trying some strange combinations of lenses and reflectors, the former were finally abandoned.

The object to be attained by the use of lenses in a light-house is, of course, identical with that which is answered by employing reflectors; and both instruments effect the same end by different means, collecting the rays which diverge from a point called the *focus*, and projecting them forward in a beam, whose axis coincides with the produced axis of the instrument. The actions by which these similar results are effected have been termed *reflection* and *refraction*. In the one case the light, as has been already said, merely impinges on the reflecting surface, and is thrown back; whilst in the other, the rays pass through the refracting medium, and are bent or refracted from their natural course.

Polyzonal lenses.

The celebrated Buffon, to prevent the great absorption of light by the thickness of the material, which would necessarily result from giving to a lens of great dimensions a figure continuously spherical, proposed to grind out of a solid piece of glass a lens in steps or concentric zones. This suggestion of Buffon, regarding the construction of large burning glasses, was first executed; with tolerable success, about the year 1780, by the Abbé Rochon; but such are the difficulties attending the process of working a solid piece of glass into the necessary form, that it is believed the only other instrument ever constructed in this manner is that which was made by Messrs Cookson of Newcastle-upon-Tyne, for the Commissioners of Northern Lighthouses.

The merit of having first suggested the building of these lenses in separate pieces seems to be due to Condorcet, who in his *Eloge de Buffon*, published so far back as 1773, enumerates the advantages to be derived from this method.¹ Sir David Brewster also described this mode of building lenses in 1811, in the *Edinburgh Encyclopædia*; and in 1822, the late eminent Fresnel, alike unacquainted with the suggestions of Condorcet, or the description by Sir David Brewster, explained, with many ingenious and interesting details, the same mode of constructing these instruments. To Fresnel belongs the additional merit of having first followed up his invention by the construction of a lens, and, in conjunction with MM. Arago and Mathieu, of placing a powerful lamp in its focus, and, indeed, of finally applying it to the practical purposes of a lighthouse. The fertile genius of the French Academician has produced many ingenious combinations of dioptric instruments for light-houses, which we shall have occasion to notice in the sequel.

Annular lenses.

The great advantages which attend the mode of construction proposed by Condorcet are, the ease of execution, by which a more perfect figure may be given to each zone, and spherical aberration almost entirely corrected, and the power of forming a lens of larger dimensions than could easily be made from a solid piece. Buffon appears only to have had in view the reduction of the thickness of the lens, but Condorcet distinctly suggests the possibility of correcting the spherical aberration by properly selected centres for the various zones.

To Fresnel, however, is due the credit of having determined these centres, which constantly recede from the axis of the lens in proportion as the zones to which they refer are removed from its centre; and the surfaces of

the zones of the annular lens, consequently, are not parts of concentric spheres, as in Buffon's lens. It deserves notice, that the first lenses constructed for Fresnel by M. Soleil had their zones polygonal, so that the surfaces were not annular, a form which Fresnel considered less accommodated to the ordinary resources of the optician. He also, with his habitual penetration, preferred the plano-convex to the double-convex form, as more easily executed. After mature consideration, he finally adopted crown glass, which, notwithstanding its greenish colour, he considered more suitable than flint glass, as being less liable to *strizæ*. All his calculations were made in reference to an index of refraction of 1.51, which he had verified by repeated experiments, conducted with that patience and accuracy for which, amidst his higher qualities, he was so remarkably distinguished. These instruments have received the name of *annular lenses*, from the figure of the surface of the zones.

Light-houses

Fig. 12.

Fig. 12 exhibits a plan and section of an annular lens of the largest size, whose focal distance is 92 centimetres, or about 36.22 inches, and which subtends a luminous pyramid of 46° of inclination, having its apex in the flame.

Having once contemplated the possibility of illuminating lighthouses by dioptric means, Fresnel quickly perceived the advantage of employing for fixed lights a lamp placed in the centre of a polygonal hoop, consisting of a series of cylindric refractors, *infinitely small* in their length, and having their axes in planes parallel to the horizon.

Such a continuation of vertical cylindric sections of various curvatures, by refracting the rays proceeding from the focus only in a direction perpendicular to the vertical sections of the cylindric parts, must distribute a zone of light *equally brilliant* in every point of the horizon. This effect will be easily understood, by considering the middle vertical section of one of the great annular lenses or burning glasses, already described, abstractly from its relation to the rest of the instrument. It will readily be perceived that this section possesses the property of refracting the rays in the vertical plane only, without interfering with azimuthal divergence; and if this section, by its revolution about a vertical axis, becomes the generating line of the enveloping hoop above noticed, such a hoop would of course possess the property of refracting an equally diffused zone of light round the horizon. The difficulty, however, of forming this apparatus, appeared so great, that Fresnel determined to substitute for it a vertical polygon, composed of what have been improperly called *cylindric lenses*, but which in reality are mixtilinear and horizontal prisms, distributing the light which they receive from the focus equally over the horizontal sector which they subtend. This polygon has a sufficient number of sides to enable it to give, at the angle formed by the junction of two of them, a light not very much inferior to what is produced by one of the sides; and upper and lower courses of curved mirrors are so placed as to make up for the deficiency of the light at the angles. The effect sought for in a fixed light is thus obtained in a much more perfect manner than by any combination of the parabolic mirrors formerly used in the British light-houses.

An ingenious modification of the fixed apparatus is due

¹ *Eloge de Buffon*, p. 35; *Œuvres de Condorcet*, tom. iv., Paris, 1804.

Light-houses.

to the inventive mind of Fresnel, who conceived the happy idea of placing one apparatus of this kind in front of another, with the axes of the cylindric pieces crossing each other at right angles. As these cylindric pieces have the property of refracting all the rays which they receive from the focus into a direction perpendicular to the mixtilinear section which generates them, it is obvious that, if two refracting media of this sort be arranged as proposed by Fresnel, their joint action will unite the rays which come from their common focus into a beam, whose sectional area is equal to the overlapped surface of the two instruments, and thus produce the effect of an annular lens. It was by availing himself of this property of crossed prisms that Fresnel invented the distinction for lights, which he calls a *fixed light varied by flashes*; in which the flashes are caused by the revolution of cylindric media, with vertical axes round the fixed-light apparatus already described.

The modification just described is shown at fig. 16. This instrument is, however, now supplanted by a revolving apparatus, consisting of alternate sections of a fixed light apparatus, and a Holophotal apparatus to be afterwards described. By the revolution of this composite apparatus the same effect is obtained, while the flash is produced by the action of a *single* optical agent, instead of by two, as in Fresnel's arrangement.

Mechanical lamp.

Fresnel immediately perceived the necessity of combining, with the dioptric instruments which he had invented, a burner capable of producing a large volume of flame; and the rapidity with which he matured his notions on this subject, and at once produced an instrument admirably adapted for the end he had in view, affords one of the many proofs of that happy union of practical with theoretical talent for which he was so distinguished. Fresnel himself has modestly attributed much of the merit of the invention of this lamp to M. Arago; but that gentleman, with great candour, gives the whole credit to his deceased friend, in a notice regarding lighthouses, which appeared in the *Annuaire du Bureau des Longitudes* of 1831. The lamp has four concentric burners, which are defended from the action of the excessive heat produced by their united flames by means of a superabundant supply of oil which is thrown up from the cistern below by a clock-work movement, and constantly overflows the wicks, as in the mechanical lamp of Carcel. A very tall chimney is found to be necessary, in order to supply fresh currents of air to each wick with sufficient rapidity to support the combustion. The carbonization of the wicks, however, is by no means so rapid as might be expected, and it is even found that, after they have suffered a good deal, the flame is not sensibly diminished, as the great heat evolved from the mass of flame promotes the rising of the oil in the cotton. So perfect, indeed, is the action of this great lamp, that it has been known to burn for upwards of twelve hours without being snuffed, or even having the wicks raised.

The annexed diagrams will give a more perfect idea of the nature of the concentric burner than can easily be conveyed by words alone.

Fig. 13 shows a plan of a burner of four concentric wicks. The intervals which separate the wicks from each other, and allow the currents of air to pass, diminish in width a little as

Fig. 13.

they recede from the centre. Fig. 14 shows a section of this burner. C, C', C'', C''' are the rack handles for raising or depressing each wick. AB is the horizontal duct which leads the oil to the four wicks; L, L', L'', L''' are small plates of tin by which the burners are soldered to each other, and which are so placed as not to hinder the free passage of the air; P is a clamping screw which keeps at the proper height the gallery R, R which carries the chimney. Fig. 15 shows the burner with its glass chimney and damper. E is the glass chimney, F is a sheet-iron cylinder, which serves to give it a greater length, and has a small damper D, capable of being turned by a handle for regulating the supply of air; and B is the pipe which supplies the oil to the wicks. The great risk in using this lamp arises from the leather valves, that force the oil by a clock-work movement, being occasionally liable to derangement; and several of the lights on the French coast, and more especially the Corduan, have been extinguished for a few minutes by the failure of the lamp, an accident which has never, and scarcely can happen with the fountain lamps which illuminate the reflectors. To prevent the occurrence of such accidents, and to render their consequences less serious, various precautions have been resorted to. Amongst others, an alarm is attached to the lamp, consisting of a small cup pierced in the bottom, which receives part of the overflowing oil from the wicks, and is capable, when full, of balancing a weight placed at the opposite end of a lever. The moment the machinery stops, the cup ceases to receive the supply of oil, and the remainder running out at the bottom, the equilibrium of the lever is destroyed, and, in falling, it disengages a spring which rings a bell sufficiently loud to waken the keeper, should he chance to be asleep. There is another precaution of more importance, which consists in having always at hand in the light-room a spare lamp trimmed and adjusted to the height for the focus, which may be substituted for the other in case of accident. It ought to be noticed, however, that it takes about twenty minutes from the time of applying the light to the wicks to bring the flame to its full strength, which, in order to produce its best effect, should stand at the height of nearly four inches (10^{cm.}). The inconveniences attending this lamp have led to several attempts to improve it; and amongst others M. Delaveleye has proposed to substitute a pump having a metallic piston, in place of the leather valves, which require constant care, and must be frequently renewed. A lamp was constructed in this manner by M. Lepaute, and tried at Corduan; but it was afterwards discontinued until some further improvements could be made upon it. It has lately been much improved by M. Wagner, an ingenious artist whom M. Fresnel employed to carry some of his improvements into effect. In the dioptric lights on the Scotch coast, a common lamp with

Light-houses.

Light-houses.

a large wick is kept constantly ready for lighting; and in the event of the sudden extinction of the mechanical lamp by the failure of the valves, it is only necessary to unscrew and remove its burner, and put the reserve-lamp in its place. The height of this lamp is so arranged, that its flame is in the focus of the lenses, when the lamp is placed on the ring which supports the burner of the mechanical lamp; and as its flame, though not very brilliant, has a considerable volume, it will answer the purpose of maintaining the light for an hour or two until the light-keepers have time to repair the valves of the mechanical lamp.

Divergence of the annular lenses.

The divergence of the annular lens is greatly less than that of the parabolic mirror. It may be estimated in the following manner. Let Δ be the angle of divergence of any ray emerging from the lens, l the distance of the point of incidence from the principal focus of the lens, and r the radius of the flame, and we have $\sin. \Delta = \frac{r}{l}$, and when Δ' is made the angle of the effective divergence of the lens, we have $\Delta' = 2\Delta$.

Adopting this rule, we find the effective divergence of the lens to be about $5^\circ 9'$, which does not differ much from the observed divergence.

Manufacture of dioptric instruments.

The manufacture of the dioptric instruments is not distinguished by any peculiarity which requires special notice, the grinding and polishing being performed by means of powders gradually increasing in fineness, successively applied as in the ordinary process of grinding glass. The zones are united by a glue which possesses the important property of being able to resist the action of considerable heat, whilst it is by no means brittle. M. Fresnel intrusted the work of building the first lens to the late M. Soleil, optician to the King of France, to whose zeal and intelligence he bears ample testimony in the *Memoire*, in which he describes the invention.

Testing of lenses.

In order to test the figure of the lenses, moulds carefully made may be applied; or the lens being mounted on a stand which permits its being set at any angle, the accuracy of the whole instrument, and of each portion of it, may be separately tested by the form and size of the spectrum which is formed in the principal focus, by permitting the solar rays to fall upon the lens at right angles. When any particular portion is to be tried, the rest of the surface is covered with discs of strong grey paper or pasteboard. Another method may be employed similar to that already described as applicable to reflectors. This method consists in finding whether a small object placed in any point of the axis farther from the lens than the principal focus, has its image refracted accurately to a point on a screen placed in the conjugate focus which is due to that distance. The same principle of testing the instrument is also applied when a person stationed at a given short distance in front of the lens observes whether its whole surface be completely illuminated by a small flame placed in the conjugate focus corresponding to that distance. All that is necessary, therefore, is to determine these distances by means of formulæ which express the relations of the distances of the object and its image. If δ represent the distance of the eye from the lens, ϕ the principal focus, and ϕ' the distance of the conjugate focus corresponding to the observer's distance δ , then we have $\phi' = \frac{\delta\phi}{\delta - \phi}$.

If, again, adopting the same notation, we wish to find the distance at which the image of an object placed at a given distance from the lens greater than that of the principal focus, should be accurately impressed on a screen, we have $\delta = \frac{\phi\phi'}{\phi' - \phi}$.

Curved mirrors.

The curved mirrors, placed above and below the lenses as a supplement to them, are, strictly speaking, generated by portions of parabolas having their foci coincident with

the common flame of the system. In practice, however, they are made portions of a curve surface, ground by the radius of the circle which osculates the given parabola, and passes tangentially through the middle of the chord which subtends the arc of the mirror. These mirrors are plates of glass, silvered on the back, and set in flat cases of sheet brass. They are suspended on a circular frame of screws, which are attached to the backs of the cases, and which afford the means of adjusting them to their true position in the light-room, so that they may reflect the horizon of the lighthouse to an observer's eye placed in the focus of the system. In order to test the accuracy of the mirrors, recourse may again be had to the formulæ of conjugate foci; thus, if we put r equal to the radius of curvature of the mirror, d equal to the given distance of any object from the mirror, and d' equal to the distance of a moveable screen, which shall receive the true image of the object if the mirror be accurately formed, we shall have for

$$\text{this latter distance } d' = \frac{rd}{2d - r}.$$

The effect of an annular lens may be estimated at moderate distances to be nearly equal to that of 3000 Argand flames of about an inch diameter; that of a cylindric refractor at about 250; and that of a curved mirror may, perhaps, on an average, be assumed at about 10 Argand flames.

Power of the annular lenses, cylindric refractors, and curved mirrors.

A beautiful apparatus, which has received the name of *catadioptric* light, from the compound action by which it is characterized, was another of Fresnel's applications of dioptric instruments to the purposes of a lighthouse. This elegant apparatus consists of thirteen rings of glass of various diameters, arranged one above another, in an oval form. The five middle rings have an interior diameter of 11.81 inches (30^{cm.}), and form a cylindric lens, similar to that already described under the head "cylindric refractors." The other rings or prisms, five of which are upper and three lower, are ground and set in such a manner that they project all the light derived from the focus in a direction parallel to the other rays by *total reflection*. This effect is produced by arranging the prisms, so that the incident rays, after being refracted at the first surface, shall strike the second side of the prism at such an angle that, instead of passing through the prism at that point, they shall be *totally reflected* from it, and, after a second refraction, emerge from the third side in a direction parallel to those transmitted by the middle or simply refracting rings. When this apparatus is employed to light only a part of the horizon, the rings are discontinued on the side next to the land, and room is thus obtained for using a common fountain lamp; but when the whole horizon is to be illuminated, the apparatus must inclose the flame on every side, so that it has in this case been found necessary to employ the hydrostatic lamp of Thilorier, in which the balance is sulphate of zinc in solution. Fresnel was prevented, by an early death, the consequence of severe application to scientific pursuits, from ever constructing this beautiful instrument; and it was reserved for the present enlightened secretary of the *Commission des Phares* to complete his brother's invention.

The nature of this apparatus will be fully understood by a reference to fig. 16, which shows its section and plan. F is the focal point in which the flame is placed, r , r cylindrical refractors, forming by their union a cylinder with a lamp in its axis, and producing a zone of light of equal intensity all round the horizon, and r' , r' are cylindric refractors having their axes at right angles to those of the refractors r , r , and revolving round them. These exterior refractors in front of the inner refractors, which have been already described under the head of Cylindric Refractors, produce, by compound refraction, a beam similar to that resulting from an annular lens. x , x

Light-houses.

Light-houses.

are catadioptric prismatic rings acting by *total reflection*, and giving out zones of light of equal intensity at every point of the horizon. The dotted lines show the course traversed by the rays of light which proceed from the lamp and are acted upon by the rings of glass. The catadioptric rings supply the places of the curved mirrors, which had at one time to be employed in the larger class of lights for a similar purpose, and as the reflection from the inner surface of a prism is, theoretically speaking, *total*, and the whole loss of light is merely that which is due to absorption in passing through the glass, and that which takes place at the two surfaces, there must of necessity be a much greater proportion of the incident light transmitted by the catadioptric action than can ever be obtained from the most perfect reflecting surface, the loss from reflection being held to be in no case less than one-half of the incident light.

The loss of light by reflection at the surface of the most perfect mirrors, and the perishable nature of the material composing their polish, induced Mr Alan Stevenson, so far back as 1835, in a report on the Light of Inchkeith, which had just been altered to the dioptric system, to propose the substitution of *totally reflecting* prisms, even in lights of the first order or largest dimensions. In this attempt he was much encouraged by the singular liberality of M. Léonor Fresnel, who not only freely communicated the method pursued by his distinguished brother Augustin Fresnel, in determining the forms of the zones of the small apparatus, introduced by him into the Harbour Lights of France, and his own mode of rigorously solving some of the preliminary questions involved in the computations; but also made various important suggestions, which substantially embrace the whole subject. The result was the preparation of a table containing Mr Stevenson's calculations of the forms of the zones of the first order, which are verifications of those of M. Fresnel; and the first catadioptric apparatus ever constructed, through the ardour and perseverance of M. François Soleil, on so magnificent a scale, was fitted up in the Skerryvore Lighthouse. In December 1843, a trial of the apparatus, attended with complete success, was made at the Royal Observatory of Paris, whereby it appeared that the illuminating effect of the cupola of zones was to that of the seven upper tiers of mirrors of the first order, as 140 to 87.

Mr Alan Stevenson having been directed by the Commissioners of the Northern Lighthouses to convert the fixed catoptric light of the Isle of May into a dioptric light of the first order, proposed that an attempt should be made to form a true cylindric, instead of a polygonal belt, for the refracting part of the apparatus; and this task was successfully completed by Messrs Cookson of Newcastle. The defect of the polygon lies in the excess of the radius of the circumscribing circle over that of the inscribed circle, which occasions an unequal distribution of light between its angles and the centre of each of its sides; and this fault

can only be fully remedied by constructing a cylindric belt, whose generating line is the middle mixtilinear section of an *annular* lens, revolving about a vertical axis passing through the principal focus. This is, in fact, the only form which can possibly produce an equal diffusion of the incident light over every part of the horizon.

In a report to the Commissioners of the Northern Lights there is the following description of the refractors constructed for the Isle of May light:—"I at first imagined," says Mr Alan Stevenson, "that the whole hoop of refractors might be built between two metallic rings, connecting them to each other solely by the means employed in cementing the pieces of the annular lenses; but a little consideration convinced me that this construction would make it necessary to build the zone at the lighthouse itself, and would thus greatly increase the risk of fracture. I was therefore reluctantly induced to divide the whole cylinder into ten arcs, each of which being set in a metallic frame, might be capable of being moved separately. The chance of any error in the figure of the instrument has thus a probability of being confined within narrower limits; whilst the rectification of any defective part becomes at the same time more easy. One other variation from the mode of construction at first contemplated has been forced upon me by the repeated failures which occurred in attempting to form the middle zone in one piece; and it was at length found necessary to divide this belt by a line passing through the horizontal plane of the focus. This division of the central zone, however, is attended with no appreciable loss of light, as the entire coincidence of the junction of the two pieces with the horizontal plane of the focus, confines the interception of the light to the fine joint at which they are cemented. With the exception of these trifling changes, the idea at first entertained of the construction of this instrument was fully realized, at the very first attempt, in the manufactory of Messrs Cookson." At a subsequent period the central zones were formed in one piece, and the arrangement of the apparatus greatly improved, by giving to the metallic frames which contain the prisms a rhomboidal¹ instead of a rectangular form. The junction of the frames being thus inclined from the perpendicular, do not in any azimuth intercept the light throughout the whole height of the refracting belt, but the interception is confined to a small rhomboidal space, whose area is inversely proportional to the sine of the angle of inclination; and when the helical joints are formed between the opposite angles of the rectangular frames, the amount of intercepted light becomes absolutely equal in every azimuth. Time and perseverance, and the patience and skill of M. François Soleil, who was urged to undertake the task, was at length crowned with success, and Mr Stevenson had the satisfaction of at last seeing a fixed light apparatus, of a truly cylindric form, with its central belt in one piece and the joints of each panel inclined to the horizon at such an angle as to render the light perfectly equal in every azimuth. Lanterns with diagonal framings are now also constructed in conformity with this arrangement of the zones.

The change of the light at the Isle of May, from the catoptric to the dioptric system, was generally acknowledged to be an improvement. A committee of the Royal Society of Edinburgh made some observations on the two lights which were exhibited in contrast on the night of the 26th of October 1836, from the town of Dunbar, which is distant about 13 miles from the lighthouse. Their report, which was drawn up by Professor Forbes, concludes in these words:—

"The following conclusions seem to be warranted:—

¹ "The form could not be exactly rhomboidal, but would be a portion of a helix intercepted between two planes, cutting the enveloped cylinder at right angles to its axis."

The cylindric form given to the refracting belts of the first order.

Light-houses.

Light-houses.

"1. That at a distance of 13 miles, the mean effect of the new light is very much superior to the mean effect of the old light (perhaps in the ratio of two to one).

"2. That at *all* distances, the new light has a prodigious superiority to the old, from the equality of its effects in all azimuths.

"3. That the new light fulfils rigorously the conditions required for the distribution of light to the greatest advantage.

"4. That at distances much exceeding 13 miles, the new light must still be a very effective one, though to what extent the committee have not observed. The light is understood to be still a good one, when seen from Edinburgh at a distance of about 30 miles."

There are few finer specimens of art than an entire apparatus for a fixed light of the first order, as shown in fig. 17. It consists of a central belt of refractors, forming a hollow cylinder 6 feet in diameter, and 30 inches high; below it are six triangular rings of glass, ranged in a cylindrical form, and above a crown of thirteen rings of glass, forming by their union a hollow cage, composed of polished glass, 10 feet high and 6 feet in diameter! There is no work of art more beautiful or more creditable to the boldness, intelligence, and zeal of the artist.

Arrangement of apparatus in the light-house.

All the lights on the dioptric principle are illuminated by a flame placed in the centre of the apparatus or common focus of the principal lenses and cylindric refractors which are ranged round it. The burner of the lamp varies in its dimensions and its consumption of oil, according to the size of the instruments employed, which also determines what is called the *order* of the light, a name expressive of its *power* and *range*. Above and below the strictly dioptric part of the apparatus of each order there are also accessory parts, which, as just described, and shown in fig. 17, consist in fixed lights of catadioptric prisms arranged in tiers, one above another, like the leaves of a Venetian blind, and placed so as to reflect to the horizon the rays received from the lamp, which is in their common focus. In all revolving lights, up till 1850, the apparatus above the principal lenses either consisted of prisms similar to those described for fixed lights, or was diacatoptric, being composed of an union of eight lenses of 19.68 inches (50^{cm}) of focal distance, inclined inwards to the flame, which is in their common focus, and thus forming a frustum of an octagonal pyramid of 50° of inclination. These upper lenses were surmounted by plane mirrors, placed so as to reflect horizontally the beams transmitted by the lenses. In placing these upper lenses, it has been thought advisable to give their axes a horizontal inclination of 7° from that of the great lenses. By this arrangement, the flash of the upper lenses always precedes that of the principal lenses.

Fig. 17.

The use of the accessory apparatus is to collect the rays, which would otherwise pass above and below the main lenses, without contributing to the brilliancy of the light. These inclined mirrors and lenses have, since 1850, been entirely laid aside on the introduction of the Holophotal system of revolving lights, to be afterwards explained, in which totally reflecting prisms form part of the *revolving* apparatus, and supersede the inclined mirrors and lenses. The nature of the whole revolving apparatus of Fresnel will be more fully understood by referring to fig. 18, which is a section

Light-houses.

Fig. 18.

of a revolving dioptric apparatus of the first order; L, L, are the great annular lenses, forming by their union an octagonal prism, with the lamp in its axis, and projecting in horizontal beams the light which they receive from the focus; a, a, upper lenses, forming by their union a frustum of an octagonal pyramid of 50° of inclination, and having their foci coinciding in the focal point. They parallelize the rays of light which pass over the lenses. b, b, plane mirrors, placed above the pyramidal lenses, and so inclined as to project the beams reflected from them in planes parallel to the horizon.

The dioptric lights used in France are divided into four orders, in relation to their power and range; but in regard to their characteristic appearances, this division does not apply, as, in each of the orders, lights of identically the same character may be found, differing only in the distance at which they can be seen, and in the expense of their maintenance. The four orders may be briefly described as follows:—

Orders of the French lights.

1st. Lights of the first order, having an interior radius or focal distance of 36.22 inches (92^{cm}), and lighted by a lamp of four concentric wicks, consuming 570^l gallons of oil per annum.

2d. Lights of the second order, having an interior radius of 27.55 inches (70^{cm}), lighted by a lamp of three concentric wicks, consuming 384 gallons of oil per annum.

3d. Lights of the third order, lighted by a lamp of two concentric wicks, consuming 183 gallons of oil per annum. The instruments used in these lights are of two kinds, one having a focal distance of 19.68 inches (50^{cm}), and the other of 9.84 inches (25^{cm}).

4th. Lights of the fourth order, or harbour lights, having an internal radius of 5.9 inches (15^{cm}), and lighted by a lamp of one wick, or Argand burner, consuming 48 gallons of oil per annum.

The great loss of light by natural divergence in the parabolic reflector, and the separation of the rays into as many system.

¹ The experience of two at the Isle of May and Inchkeith, shows that the annual expenditure of spermaceti oil, in lights of the first order, does not exceed 570 gallons.

Lighthouses.

Lighthouses.

portions as there are lenses in the frame, in Fresnel's revolving dioptric apparatus, together with the objectionable plan for intercepting the rays which pass above and below the lenses, led Mr Thomas Stevenson to inquire into the possibility of increasing the intensity of lights by changes in the optical arrangements. The parabolic reflectors act chiefly on the *posterior* portion of the flame, and generally receive about $\frac{1}{4}$ ths of the whole luminous sphere, while a series of dioptric instruments can affect only an *anterior* cone, amounting to about $\frac{1}{4}$ ths. Certain deductions, due to the form of the flame and the loss by reflection and refraction, reduce these numbers to $\frac{1}{8}$ d for the reflectors, and $\frac{1}{10}$ ths for the lenses, as the amount of light actually given forth by each system. Both arrangements are, therefore, so far unsuitable for revolving lights, in which the concentration of all the diverging rays into pencils of parallel rays is the grand object to be aimed at. The problem which Mr Stevenson assigned to himself was to *produce the brightest beam from a given flame by the smallest number of reflections and refractions*. This object he attained partly by combining dioptric with catoptric and catadioptric action, and partly by an *extension of the lenticular action itself over a greater subtense*. To this arrangement the name of *Holophotal* has been given, to signify the useful application of the *whole* of the light.

One mode of producing this effect is to combine an an-

Fig. 19.

nular lens L, figs. 19 and 20; a parabolic conoid *a*, truncated at its parameter; and hemispherical mirror *b*. The lens, when at its proper focal distance from the flame, subtends the same angle from it as the outer lips of the paraboloid. The hemispherical reflector occupies the place of the parabolic conoid which has been cut off behind the parameter. The flame is at once in the centre of the hemispherical mirror and in the common

focus of the lens and paraboloid. Suppose the whole sphere of rays emanating from the flame to be divided into two portions, viz., the hemisphere of front rays and the hemisphere of back rays. Part of the anterior hemisphere of rays is intercepted by the lens and made parallel by its action, while the remainder is intercepted by the paraboloidal surface, and made parallel by its action. The rays forming the posterior hemisphere, and which fall upon the hemispherical reflector, are sent back through the focus in the samelines, but in directions opposite to those in which they came, whence passing onwards they are in part refracted by the lens, while the rest are made parallel by the paraboloid. The back rays thus finally emerge horizontally in union with the light from the anterior hemisphere. This instrument, therefore, fulfils the conditions prescribed, by collecting the *entire sphere of diverging rays into one parallel beam of light*.

Fig. 20.

The first instrument constructed upon this principle was for the North Harbour of Peterhead, where it has been in use since August 1849. Mr A. Stevenson has also adopted an instrument of this kind, on a large scale, in Hoy Sound Lighthouse, one of the Northern Lights' stations.

Experiments were lately made at Gullan Hill to test the comparative power of an instrument on this principle (the reflecting part being of brass, and but roughly finished), and a highly-finished silver reflector of the usual construction; both instruments being 25 inches in diameter at the lips. The lights were viewed at distances of from 7 to 12 miles every night during a week, and in every instance the brass reflector on the holophotal principle had the advantage of the silver reflector; and on one occasion, when the atmosphere was thick, the light from the holophotal brass reflector was alone visible.

In so far as concerns the arrangement of the different parts, irrespective of the nature of the materials of which they are composed, the light emitted from any given flame by the instruments just described, should be the light of *maximum intensity*. But the most accurate experiments which have been undertaken by scientific observers have shown that reflection from the best silvered mirrors, and even from metallic specula made with the utmost care for experimental purposes, involves a loss of light by absorption of not less than about one-half of the whole incident rays.

The advantage of employing as largely as possible the principle of *total reflection* from glass, in place of ordinary reflection from metallic specula, induced Mr T. Stevenson to attempt further improvements in the holophotal system of illumination. If we retain the lens and the spherical mirror of the holophotal apparatus just described, and, in place of the paraboloid, conceive the arc between the lens and the spherical mirror to be filled up with glass rings, which are the solids of revolution generated by the rotation of the cross section of the totally reflecting prisms used in fixed lights, round a horizontal axis passing through the flame, we shall then have *extended the action of the lens, so as to parallelize one-half of the whole sphere of incident rays*. Such an arrangement is shown in figs. 21 and 22, where L

Fig. 21.

Fig. 22.

is the lens, *p* the totally reflecting prisms, and *b* is the spherical mirror. The distinguishing peculiarity of this arrangement is, that the prisms, instead of transmitting the light in parallel vertical plates, diverging all round as in the fixed light apparatus of Fresnel, produce an extension of the lenticular or *quaquaversal* action of the common annular lens, by assembling the light around its axis in the form of concentric hollow cylinders. In order to distinguish this system of prisms from those introduced by M. Fresnel, which have no lenticular action, they may therefore be termed *catadioptric lenses*.

The writer of this article has lately heard, that, although it had never been proposed to use such prisms for lighthouse purposes, a small lamp, for lighting the quays of a canal in Paris, was made by M. A. Fresnel, in 1824, in which some prisms, similar to those above described, formed an accessory part; but no drawing or description of such an apparatus was ever published, and all knowledge of it seems to have been

Light-houses.

lost till Mr T. Stevenson described his plan in 1849. Since that time, thirty-six instruments have been made at Edinburgh, on the small scale, both for home and foreign use. The first instance in which those prisms were ever applied to lighthouses was at the Horsburgh Light, near Singapore, the optical part of which was designed by Mr T. Stevenson. This was the first time that the principle of total reflection was applied to the moving apparatus of revolving lights. The first light of the large order, on this principle, was constructed under the direction of Mr Alan Stevenson, for North Ronaldsay, in the Orkneys; and seven others have recently been made in Paris for French and American light-houses. There can be no doubt that this arrangement will be generally adopted, instead of the combination of inclined lenses and plane mirrors, first employed at Corduan, and subsequently in other revolving lights in France and Britain.

Catadioptric glass mirror.

By an elegant adaptation of *totally reflecting zones*, Mr Thomas Stevenson has further succeeded in substituting, for a reflector of metal or silvered glass, a *polyzonal totally reflecting hemisphere of glass* (vide fig. 5). By this arrangement, reflection from metallic specula is abolished from every part of the system, and the principles of total reflection and simple refraction alone are employed.

The action of these glass zones will be best understood by referring to fig. 23, which gives the cross section of one

Fig. 23.

of them; f shows the flame or centre of the system, and the diverging rays are represented by dotted lines, the arrows indicating the direction of a ray before and after being altered by the prism. The side bc is concave, the centre of curvature being in f , the centre of the flame. The surfaces of the other sides, ab , and ac , are portions of parabolas, whose common focus is f , or of circles osculating the parabolic curves. Those parabolic surfaces face each other, and their tangents form an angle of 90° with each other at the vertex of the prism. Any ray proceeding from the centre f will be received as a normal to the surface bc , and will consequently pass on without suffering any deviation at e , where it meets the prism, to its incidence on the surface ab , where

Fig. 24.

it will be totally reflected in the direction rr' , tangential to the sphere at the axis of each zone. At r' it again suffers

total reflection, and finally emerges in a radial direction without deviation at the point e' . An exactly similar action will take place simultaneously with another ray in the same path from the flame, though passing in an opposite direction. The concentric zones, a , which compose the dome (vide fig. 24), are solids of revolution, generated by the rotation round the horizontal axis of the instrument of triangles similar to a, b, c (fig. 23), with a radius equal to af . The angle formed by the radius with the horizontal axis of the instrument varies from nearly 90° down to zero, as shown in fig. 24. Where those angles vanish at a' , a conoid will result, having the radius of its base equal to the semichord of its inner surface. It will be seen that the prisms b, a, c , fig. 23, resemble in their action that of the drops of rain which give rise to the phenomenon of the *secondary* rainbow. In fig. 24, which shows the whole instrument complete, L represents the common lens acting on the rays by refraction only; p , the catadioptric portion of the lens acting by refraction and total reflection; and a, a', a , the prisms acting by total reflection only. Part of a hemispherical dome on this principle has now been successfully executed.

Fig. 25 shows the adaptation of the holophotal system to Fresnel's revolving light of the first order. L, L are the lenses, and p, p the catadioptric lenticular rings. The advantage of this system will clearly appear by comparing it with Fresnel's apparatus (fig. 18). At each of figs. 25 and 18, diagrams marked xy show proportionate sections of the beam of light given out by the two arrangements respectively. The objectionable arrangement of the lenses and mirrors a and b (fig. 18), in which so much of the light is lost, by the introduction of so many surfaces, and is also superseded.

Fig. 25.

Adaptation of the Holophotal system to Fresnel's Apparatus.

For pointing out sunken reefs, on which no lighthouse Dipping can be placed, two plans have been proposed by Mr Thomas Stevenson. The first, or *dipping* light, consists in throwing a pencil of rays from a lantern on shore *down* upon the reef, by inclining the vertical axis of the apparatus at the requisite angle; and by this arrangement the visibility of the light is confined within certain limits, the passing within which is, to the seaman, a sign of danger, and a warning to *haul off* seaward. The second, or *apparent* light, applies to reefs on which a small beacon, capable of bearing a cage on its top, can be built, but which affords no room for a lighthouse tower. In this cage is placed some *reflecting* apparatus, either wholly *catadioptric*, or combining a *plane mirror* with a vertical system of straight lenticular prisms; and upon this there is projected, from a lantern on shore, a beam of light, which is diverted (according to the angle at which the cage apparatus on the beacon is set) into any given direction that may be required. This latter plan has been most successfully applied to the entrance of Stornoway Loch, a much-used harbour of refuge in the Lewis, and has drawn from many shipmasters frequenting that port written expressions of their satisfaction with the light, which is well seen *a mile and a half* in the offing: a distance amply sufficient for the limited purposes for which such lights should be used. The name *apparent* is given to this light, because, while it is really produced by a flame on shore, it *seems* to proceed from the beacon on the rock.

In all fixed lights of the present construction, which are

Light-houses.

Light-houses. not required to show all round the horizon, the light of the darkened part is either allowed to be lost, or is returned through the focus by means of a portion of a spherical mirror. There are, however, cases frequently occurring to the lighthouse engineer where it would be very desirable to employ this spare light, not in the direction diametrically opposite to the darkened arc, but in some other direction more suited to the configuration of the coast. The apparatus for Isle Oronsay, of which fig. 26 is a horizontal section through

Holophotal condensers for illuminating narrow sounds.

Light-houses.

Fig. 26.

the focus, is the first which has been designed with a view to the most advantageous employment of this spare light.

The lighthouse of Isle Oronsay is situate in the narrow Sound of Skye, and, throughout nearly the whole of the illuminated arc, does not require to be seen to a greater distance than 3 or 4 miles, while in one direction (down the sound) it can be seen for 15 miles, and in another (up the sound) it can be seen for about 7 miles. If, therefore, a light were erected sufficiently powerful to be seen at the greatest distance required, it must be very greatly too powerful in every other direction, and consequently there would be a great waste of oil; while, if an apparatus only powerful enough for the short range were employed, it would become necessary to make use of subsidiary apparatus, implying additional lamps, and an increased expenditure of oil, to show up and down the sound. The apparatus shown was designed by Mr T. Stevenson, with the view of reinforcing the ordinary fixed-light apparatus in the directions of greatest range. This is effected by distributing in these directions the spare light on the dark side of the lantern, which, if returned through the focus in the ordinary manner by means of a spherical mirror, would only tend to strengthen that portion of the light which is already sufficiently powerful.

A is 167° of a small fixed-light apparatus subtending the entire arc to be illuminated; so that all the rest of the light, or 193° , is spare light. Of this, 129° are parallelized by the holophotal apparatus B; and the rays, falling on a series of equal and similar prisms, *a*, are again refracted, but in the horizontal plane only; and after passing through a focal point (independent for each prism), emerge in a series of twelve equal and parallel beams, having a divergence of about 10° , which are also equal and parallel to the diverging beam, *a*, and, consequently, according to well known optical laws, have the effect of strengthening it as much as if they were actually superimposed upon it. As the light of 139° is, in this manner, condensed into about 10° , the effect must be from 12 to 14 times that of the unassisted apparatus, and

should, therefore, be amply sufficient for a range of 15 miles. In like manner, the light parallelized by the other holophote C, are refracted by the prisms *b*, so as to strengthen the arc β , which will thus be rendered amply powerful for a range of 7 miles. The greater number of rays in the arcs α and β are intended to indicate the additional density due to the action of the subsidiary prisms. We shall only add, that when arcs of coloured light are to be employed, this method of strengthening any particular portion of the light becomes very important, as offering a ready method of equalizing the general range, otherwise interfered with by the enormous absorption of coloured media; and we might suggest, that, even where the light requires to be shown all round, it is possible to supplement any arc at the expense of any other, by cutting off an ordinary apparatus by a horizontal plane at any suitable height, and mounting a portion of a holophote and a series of prisms above it. By a somewhat similar arrangement to what has been described for Oronsay, the whole of the rays proceeding from a plane may be spread over any desired arc of the horizon.

Having thus fully described the catoptric and dioptric systems of illumination, it might be expected that we should institute a comparison between them. This, however, may now be considered unnecessary, as the universal adoption of the dioptric system speaks for itself. Its advantages are indeed too numerous and too palpable to be overlooked, combining, as they do, efficiency of action and fitness to meet every requirement, with economy in the consumption of oil; and we may safely say, that in all those countries where this important branch of administration is conducted with the care and solicitude which it deserves, the dioptric system has been adopted to the complete exclusion of the catoptric, except, indeed, in certain cases where economy of first construction and simplicity of detail are objects of primary importance.

General remarks.

To the Dutch belongs the honour of having first, *after the French*, embraced the system of Fresnel in their lights. The Commissioners of the Northern Lights followed in the train of improvement, and, in 1834, sent Mr Alan Stevenson on a mission to Paris, with full power to take such steps for acquiring a perfect knowledge of the dioptric system, and forming an opinion on its merits, as he should find necessary. The singular liberality with which he was received by M. Léonor Fresnel, brother of the late illustrious inventor of the system, and his successor as the Secretary of the Lighthouse Commission of France, afforded Mr A. Stevenson the means of making such a report on his return as induced the Commissioners to authorize him to remove the reflecting apparatus of the revolving light at Inchkeith, and substitute dioptric instruments in its place. This change was completed, and the light exhibited on the evening of 1st October 1835; and so great was the satisfaction which the change produced, that the Commissioners immediately instructed Mr Stevenson to make a similar change at the fixed light of the Isle of May, where the new light was exhibited on the 22d September 1836. The Trinity House of London followed next in adopting the improved system, and employed Mr A. Stevenson to superintend the construction of a revolving dioptric light of the first order, which was afterwards erected at the Start Point in Devonshire. Other countries followed, and the *Report of the Lighthouse Board of America*, published in 1852, which recommends (p. 13) the adoption of Fresnel's dioptric system, and the holophotal improvements, is a very full body of information on lighthouse subjects, extending over about 750 pages. Even Turkey has followed in the train of improvement, and we believe that a light on the dioptric principle will shortly be exhibited (if it be not already completed) from the Isle of Serpents. Fresnel, who is already classed with the greatest of those inventive minds which extend the boundaries of human knowledge, will thus, at the same

Light-houses.

time, receive a place amongst those benefactors of the species who have consecrated their genius to the common good of mankind; and, wherever maritime intercourse prevails, the solid advantages which his labours have procured will be felt and acknowledged.

When, however, this system was in its infancy, there were several objections raised to its adoption, which appeared to be of very considerable importance, though the experience of years has proved that they are not insurmountable. The first, and probably the most important, was the liability of the lamp to be extinguished from the failure of the leather work of the oil-pumps—a most serious objection, inasmuch as, from there being only one lamp, its failure implies the extinction of the light. The means adopted to remedy this have been already described (*vide* “mechanical lamp”), and an experience of twenty-one years in the Northern Lighthouses has proved them to be sufficient for the purpose; for during the whole of that time (although it has on several occasions been necessary to light the spare lamp) the light has only on one occasion been totally extinguished, a casualty which was caused by the keeper sleeping on his watch.

The only other objection worthy of mention is the short duration of the flash in revolving lights, owing to the small divergence ($5^{\circ} 9'$) of the annular lens. This has been corrected by setting the inclined mirrors, or holophotal prisms, a little in advance of the great lenses, so that they precede, and consequently prolong, the principal flash. M. Degrand has also proposed to cut the whole apparatus by a horizontal plane passing through the focus, and to set one portion a few degrees in advance of the other, a plan which has considerable advantages, as all the portions of the beam are more nearly of equal intensity.

Spherico-cylindric lenses.

Mr T. Stevenson, moreover, suggests an ingenious method of remedying this evil, by constructing lenses whose aberration in the vertical plane is corrected, while that in the horizontal plane may be adjusted to any determinate amount. In the application of this method of construction to the annular lenses they would be ground on the external surface as before; but the internal surface would be a portion of a vertical cylinder of suitable radius. Thus each vertical section would be similar to that of a plano-convex lens as at present, and would refract the rays accordingly, while the horizontal sections would be of a meniscal form, and would act only by the excess of their convexity over their concavity. Thus, by varying the radius of the cylinder, any amount of horizontal divergence may be obtained, and this without much increasing the thickness of the glass, at least in the case of revolving lights, in which a curve of long radius might be applied.

Fuel of light-houses.

The oil, until lately, most generally employed in the lighthouses of the United Kingdom was the sperm oil of commerce, which is obtained from the South Sea whale (*Physeter macrocephalus*). In France, the colza oil, which is expressed from the seed of a species of wild cabbage (*Brassica oleracea colza*), and the olive oil, are chiefly used; and a species of the former has now been successfully introduced into the British lighthouses.

The advantages of the colza oil are thus stated by the engineer of the Scottish Lighthouse Board:—

“It appears from pretty careful photometrical measurements of various kinds, that the light derived from the colza oil is, in point of intensity, a little superior to that derived from the spermaceti oil, being in the ratio of 1.056 to 1. The colza oil burns both in the Fresnel lamp and the single Argand burner with a thick wick during seventeen hours, without requiring any coaling of the wick or any adjustment of the damper; and the flame seems to be more steady and freer from flickering than that derived from spermaceti oil. There seems (most probably owing to the greater steadiness of the flame) to be less breakage

of glass chimneys with the colza than with the spermaceti oil.

Light-houses.

The consumption of oil seems in the Fresnel lamp to be 121 for colza, and 114 for spermaceti; while in the common Argand, the consumption appears to be 910 for colza, and 902 for spermaceti; and if we assume the means of these numbers, 515 for colza, and 508 for spermaceti, as representing the relative expenditure of these oils; and if the price of colza be 3s. 9d., while that of spermaceti is 6s. 9d. per imperial gallon; we shall have a saving in the ratio of 1 to 1.755, which, at the present rate of supply for the Northern Lights, would give a saving of about L.3266 per annum.”

In a few lighthouses which are near towns, the gas of Gas-pit coal has been used; and there are certain advantages, more especially in dioptric lights, where there is only one large central flame, which would render the use of gas desirable. The form of the flame, which is an object of considerable importance, would thus be rendered less variable, and could be more easily regulated, and the inconvenience of the clock-work of the lamp would be wholly avoided. But it is obvious that gas is by no means suitable for the majority of lighthouses, their distant situation, and generally difficult access, rendering the transport of large quantities of coal expensive and uncertain; whilst in many of them there is no means of erecting the apparatus necessary for manufacturing gas. There are other considerations which must induce us to pause before adopting gas as the fuel of lighthouses; for, however much the risk of accident may be diminished in the present day, it still forms a question, which ought not to be hastily decided, how far we should be justified in running even the most remote risk of explosion in establishments such as lighthouses, the sudden failure of which might involve consequences of the most fatal description, and the situation of which is often such, that their re-establishment must be a work of great expense and time.

The application of the Drummond and Voltaic lights to lighthouse purposes is, owing to their prodigious intensity, a very desirable consummation; but it is surrounded by so many practical difficulties, that it may, in the present state of our knowledge, be pronounced unattainable. The uncertainty which attends the exhibition of both these lights is of itself a sufficient reason for coming to this conclusion. But other reasons unhappily are not wanting. The smallness of the flame renders those lights wholly inapplicable to dioptric instruments, which require a great body of flame, in order to produce a degree of divergence sufficient to render the duration of the flash in revolving lights long enough to answer the purpose of the mariner. M. Fresnel made some experiments on the application of the Drummond light to dioptric instruments, which completely demonstrate their unsuitability for this combination. He found that the light obtained by placing it in the focus of a great annular lens was much more intense than that produced by the great lamp and lens of Corduan; but the divergence did not exceed $30'$; so that, in a revolution like that of Corduan, the flashes would last only $1\frac{1}{2}$ second, and would not, therefore, be seen in such a manner as to suit the practical purposes of a revolving light. The great cylindrical refractor, used in fixed lights of the first order, was also tried with the Drummond light in its focus; but it gave coloured spectra at the top and bottom, and only a small bar of white light was transmitted from the centre of the instrument. The same deficiency of divergence completely unfits the combination of the Drummond light with the reflector for the purposes of a fixed light, and even if this cause did not operate against its application in revolving lights on the catoptric plan, the supply of the gases, which is attended with almost insurmountable difficulties, would, in any case, render the maintenance of the light precarious and uncertain in the last degree.

There are many questions of much interest regarding

Light-
houses.

General
questions
regarding
lighthouses

Distinction
and distri-
bution of
lights.

lighthouses, which appear to open an extensive field of inquiry; and it may be doubted whether some of them have received that degree of consideration to which their importance entitles them. Amongst these we may rank the numerous questions which may be raised regarding the most effective kind of distinctions for lights. Those distinctions may be naturally expected to be the most effective which strike an observer by their *appearance* alone. Thus a red and white light, a revolving and a fixed light, offer *appearances* which are calculated to produce upon the observer a stronger sense of their difference than the same observer would receive from lights the sole difference of which lies in their revolutions being performed in greater or less intervals of time. On the other hand, the distinctions derived from time, if the intervals on which they depend do not approach too closely to each other, appear to afford very suitable means for characterizing lights; and the number of distinctions which may be founded upon time alone are pretty numerous. Coloured media have the great disadvantage of absorbing light, and the only colour which has hitherto been found useful in practice is red, all others, at even moderate distances, serving merely to enfeeble, without characterizing, lights. In the system of Fresnel, as already explained, all the distinctions are based upon time alone. Mr Robert Stevenson, the engineer of the Northern Lighthouses, has invented two distinctions, which, although they are produced by variations of the time, possess characteristic *appearances*, sufficiently marked to enable an observer to distinguish a light without counting time. The one is called a *flashing* light, in which the flashes and eclipses succeed each other so rapidly as to give the appearance of a succession of brilliant scintillations; and the other has been called *intermittent*, from its consisting of a fixed light, which is suddenly and totally eclipsed, and again as suddenly revealed to view. The effect of this light is entirely different from that of any revolving light, both from the great inequality of the intervals of light and darkness, and also from the contrast which is produced by its sudden disappearance and reappearance, which is completely different from the gradual diminution and increase of the light in revolving lights, more especially in those on the catoptric principle. The great and still increasing number of lights renders the means of distinguishing them one of the most important considerations connected with lighthouses.

Arrange-
ment of
lights on
the coast.

Not less important, and very nearly allied to the subject of distinction, is that of the arrangement of lights on a line of coast. The choice of the most suitable places, and the assigning to each the characteristic appearances which are most likely to distinguish it from all the neighbouring lights, are points requiring much consideration; and it ought never to be forgotten, that the indiscriminate erection of lighthouses soon leads to confusion, and that the needless exhibition of a light, by involving the loss of a distinction, may afterwards prove inconvenient in the case of some future light, which time and the growing wants of trade may call for on the same line of coast. To enter at length upon this topic, or even to lay down the general principles which ought to regulate the distribution of lights, would exceed the limits of this article; but in connection with this it may be observed, that the superintendence of lighthouses should be committed to one general body, and ought not to be left to local trusts, whose operations are too often conducted on narrow principles, without reference to general interests. The inconveniences arising from interference between the distinctions of the lights under one trust, and those of the lights under another, are thereby avoided; and the full advantage is obtained of the means of distinction at the disposal of both.

The considerations which enter into the choice of the position and character of the lights on a line of coast are either, on the one hand, so simple and self-evident as

scarcely to admit of being stated in a general form, without becoming mere truisms; or are, on the other hand, so very numerous, and often so complicated, as scarcely to be susceptible of compression into any general laws. We shall not, therefore, do more than very briefly notice, in the form of distinct propositions, a few of the chief considerations which should guide us in the selection of the sites and characteristic appearance of the lighthouses to be placed on a line of coast.

1. The most prominent points of a line of coast, or those first made on *over-sea* voyages, should be first lighted; and the most powerful lights should be adapted to them, so that they may be discovered by the mariner as long as possible before his reaching land. 2. So far as is consistent with a due attention to distinction, revolving lights of some description, which are necessarily more powerful than fixed lights, should be employed at the outposts on a line of coast. 3. Lights of precisely identical character and appearance should not, if possible, occur within a less distance than 100 miles of each other on the same line of coast, which is made by over-sea vessels. 4. In all cases, the distinction of colour should never be adopted except from absolute necessity. 5. Fixed lights, and others of less power, may be more readily adopted in narrow seas, because the *range* of the lights in such situations is generally less than that of open sea-lights. 6. In narrow seas, also, the distance between lights of the same appearance may often be safely reduced within much lower limits than is desirable for the greater sea-lights. Thus there are many instances in which the distance separating lights of the same character need not exceed 50 miles; and peculiar cases occur in which even a much less separation between similar lights may be sufficient. 7. Lights intended to guard vessels from reefs, shoals, or other dangers, should, in every case where it is practicable, be placed *seaward* of the danger itself, as it is desirable that seamen be enabled to *make* the lights with confidence. 8. Views of economy in the first cost of a lighthouse should never be permitted to interfere with placing it in the best possible position; and, when funds are deficient, it will generally be found that the wise course is to delay the work until a sum shall have been obtained sufficient for the erection of the lighthouse on the best site. 9. The elevation of the lantern above the sea should not, if possible, for sea-lights, exceed 200 feet; and about 150 feet is sufficient, under almost any circumstances, to give the range which is required. Lights placed on high headlands are subject to be frequently wrapped in fog, and are often thereby rendered useless at times when lights on a lower level might be perfectly efficient. But this rule must not, and indeed cannot, be strictly followed, especially on the British coast, where there are so many projecting cliffs, which, while they subject the lights placed on them to occasional obscuration by fog, would also entirely and permanently hide from view lights placed on the lower land adjoining them. In such cases, all that can be done is carefully to weigh all the circumstances of the locality, and choose that site for the lighthouse which seems to afford the greatest balance of advantage to navigation. As might be expected, in questions of this kind, the opinions of the most experienced persons are often very conflicting, according to the value which is set on the various elements which enter into the inquiry. 10. The best position for a sea-light ought rarely to be neglected for the sake of the more immediate benefit of some neighbouring port, however important or influential; and the interests of navigation, as well as the true welfare of the port itself, will generally be much better served by placing the sea-light *where it ought to be*, and adding, on a smaller scale, such subsidiary lights as the channel leading to the entrance of the port may require. 11. It may be held as a general maxim, that the fewer lights that can be employed in the illumination of a coast the

Light-
houses.

Lightfoot. better, not only on the score of economy, but also of real efficiency. Every light needlessly erected may, in certain circumstances, become a source of confusion to the mariner; and, in the event of another light being required in the neighbourhood, it becomes a *deduction* from the means of distinguishing it from the lights which existed previous to its establishment. By the needless erection of a new lighthouse, therefore, we not only expend public treasure, but waste the means of distinction among the neighbouring lights. 12. Distinctions of lights, founded upon the minute estimation of intervals of time between flashes, and especially on the measurement of the duration of light and dark periods, are less satisfactory to the great majority of coasting seamen, and are more liable to derangement by atmospheric changes, than those distinctions which are founded on what may more properly be called the *characteristic appearance* of the lights, in which the times for the recurrence of certain appearances differ so widely from each other as not to require for their detection any very minute observation in a stormy night. Thus, for example, flashing lights of five seconds' interval, and revolving lights of half a minute, one minute, and two minutes, are much more characteristic than those which are distinguished from each other by intervals varying according to a slower series of 5", 10", 20", 40", &c. 13. Harbour and local lights, which have a circumscribed range, should generally be fixed instead of revolving; and may often, for the same reason, be safely distinguished by coloured media. In many cases, also, where they are to serve as guides into a narrow channel, the leading lights which are used should, at the same time, be so arranged as to serve for a distinction from any neighbouring lights. 14. Floating lights, which are very expensive, and more or less uncertain, from their liability to drift from their moorings, as well as defective in power, should never be employed to indicate a turning-point in a navigation in any situation where the conjunction of lights on the shore can be applied at a reasonable expense.

British and Irish Lights.

In concluding, it may be necessary to state that the English lights are placed under the Corporation of Trinity House of Deptford, Stroud; the Scottish lights are under the management of the Commissioners of Northern Lights; and the Irish lights are under the care of the Corporation for preserving and improving the port of Dublin, commonly called the Ballast Board.

Last act of parliament, 16th and 17th Vict., cap. 131. The last act of parliament on the subject of lighthouses forms part of one the general title of which is, "An act to amend various laws relating to merchant shipping." It passed 20th August 1853. The chief provisions which affect lighthouses are the following:—1. The light dues of the United

Kingdom are to form one *imperial* fund, under the control of the Board of Trade. 2. From this fund all expenses of erecting and maintaining the lights of the United Kingdom are to be defrayed. 3. The three boards which manage the lighthouses in England, Scotland, and Ireland are to render account of their expenditure to the Board of Trade. 4. The Trinity House, or English board, is to exercise a certain control over the boards in Scotland and Ireland, and is to judge of all their proposals to erect new lights, or to change existing ones; but in every case the sanction of the Board of Trade must precede the acts of each of the three boards.

Lightfoot.

The following works may be consulted on the subject of lighthouses:—Smeaton's *Narrative of the Eddystone Lighthouse*, Lond. 1793; Stevenson's *Account of the Bell-Rock Lighthouse*, Edinburgh, 1824; Belidor, *Architecture Hydraulique*, vol. iv., p. 151; Peclet, *Traité de l'éclairage des Phares*, Paris, 1827; Fresnel's *Memoire sur un Nouveau Système d'éclairage des Phares*, Paris, 1822; Admiral de Rosset's *Rapport, contenant l'Exposition du Système adopté par la Commission des Phares pour éclairer les Côtes de France*, Paris, 1825; *Treatise on Burning Instruments*, containing the method of building large polyzonal lenses, by D. Brewster, LL.D., F.R.S., Edin. 1812; *Fanale di Salvo, nell' Istria, Illuminato a Gaz*, Vienna, 1821; *On Construction of Polyzonal Lenses and Mirrors of Great Magnitude, for Lighthouses, &c.*, by D. Brewster, LL.D., F.R.S. (*Edin. Phil. Jour.*, 1823, vol. viii., p. 160); *Account of a New System of Illumination for Lighthouses*, by D. Brewster, LL.D., F.R.S., Edin. 1827; *Saggio di Osservazione, &c.*, or *Observations on the Means of Improving the Construction of Lighthouses*; with an Appendix, on the Application of Gas to Lighthouses, by the Chevalier G. Aldini, Milan, 1823; Bordier Marcet's *Notice descriptif d'un Fanal à double aspect, &c.*, Paris, 1823; Bordier Marcet's *Parabole Soumise à l'art, ou Essai sur la Catoptrique de l'éclairage*, Paris, 1819; L. Fresnel, Paris, 1836; Stevenson's *Sketch of Civil Engineering in America*, London, 1838, p. 296; *Report of Select Committee of the House of Commons on Lighthouses*, 1834; *Report by a Committee of the Board to the Commissioners of the Northern Lighthouses, on the "Report of the Select Committee," 1836*; *Report to the Commissioners of the Northern Lighthouses on the Illumination of Lighthouses*, by Alan Stevenson, M.A., Edin., 1834; *Report to the same Board, on the Inchkeith Dioptric Light*, by Alan Stevenson, Edin., 1835; *Report on the Isle of May Dioptric Light*, by Alan Stevenson, 1836; *Report on the Isle of May Light*, by a Committee of the Royal Society (Professor Forbes, reporter), Edin. 1836; *Account of Skerryvore Lighthouse, with Notes on Lighthouse Illumination*, by Alan Stevenson, LL.B., Edin., A. & C. Black, 1847; Stevenson's *Treatise on the History, Construction, and Illumination of Lighthouses*, London, 1850; *Account of the Holographical System of Illuminating Lighthouses*, by Thomas Stevenson, F.R.S.E., C.E., in the *Transactions of the Royal Scottish Society of Arts* for 1849; *Formulas for Constructing Totally Reflecting Hemispherical Mirrors*, by William Swan, F.R.S.E., *Trans. Roy. Scott. Soc. of Arts*, 1850; *Description of Spherico-Cylindric Lenses, &c.*, by T. Stevenson, F.R.S.E., *Edinburgh New Philosophical Journal*, 1855; *Report of the Lighthouse Board of America*, Washington, 1852. (A. S.—N.)

LIGHTFOOT, JOHN, a learned commentator, was the son of a clergyman, and was born at the rectory of Stoke-upon-Trent, in March 1602. After receiving his elementary education at Moreton Green, near Congleton, he entered, in 1617, Christ's College, Cambridge, where he applied himself to the study of the learned languages, and was reputed the best orator among the under-graduates. At the age of nineteen he became Bachelor of Arts; and leaving the university, acted as usher for two years in a school at Repton, in Derbyshire. He then took orders, and was appointed curate of Norton-under-Hales, in Shropshire. While chaplain in the family of Sir Rowland Cotton, he became imbued with an enthusiasm for the study of Hebrew; and shortly afterwards, resigning his cure, he removed to London, in order to devote his time wholly to study. Here, after a short stay, he formed the design of

travelling abroad, but was prevailed on to become pastor of Stone, in his native county. This charge he quitted in 1628, a short time after his marriage, and removed to Hernsey, near London, for the purpose of consulting Sion College Library in the course of his studies. In 1629 appeared his first work, *Erubhim, or Miscellanies, Christian and Judaical*. Sir Rowland Cotton, to whom it was dedicated, presented him, in 1630, to the rectory of Ashley, in Staffordshire.

Lightfoot now devoted himself ardently and exclusively to the study of the Scriptures; and in order to superintend the publication of his researches, he, in 1642, again repaired to London, where he was appointed minister of St Bartholomew's, behind the Exchange. On account of his great biblical learning, he was nominated a member of the Assembly of Divines, and in their councils he was a bold and

Ligor
||
Liguria.

hearty friend of the Presbyterian party. He preached before the House of Commons in March 1643, and was soon after nominated by the parliamentary visitors Master of Catherine Hall, Cambridge. At the close of the year he was presented to the rectory of Great Munden, in Hertfordshire. In 1644 appeared the first part of his *Harmony*, accompanied by an outline of the entire work, which was slowly filled in during the later years of his life. Having taken the degree of Doctor in Divinity in 1652, he was elected Vice-Chancellor of the University of Cambridge in 1655, and was about the same time engaged in revising the Polyglott Bible as it went to the press. At the Restoration his mastership of Catherine Hall, which he had offered to resign, was confirmed to him, along with his living of Great Munden. A prebend in the church of Ely was also bestowed upon him by Lord-Keeper Bridgman. In 1661 he was appointed one of the assistants at the conference upon the Liturgy; but, disliking the heat of controversy, he soon ceased to attend, and retired to Munden, where a cordial affection subsisted between him and his rustic flock. Favoured by a healthy constitution and by abstemious habits he continued till his death, December 6, 1675, to labour at his *Harmony*.

Dr Lightfoot's fame rests upon his intimacy with Rabbinical learning, and in this no English commentator has ever surpassed him. A collection of his works was first printed in 2 vols. folio in 1684, and supplemented by an 8vo volume of *Remains* in 1700. The best edition is edited, with a life of the author, by the Rev. J. R. Pitman, A.M., 13 vols., London, 1825.

LIGOR, a seaport-town and capital of a cognominal state in Lower Siam, Malayan Peninsula, situate at the mouth of the Ligor River, which here enters the Gulf of Siam opposite the island of Tantalén, N. Lat. 8. 25., E. Long. 100. 10. It is encompassed by a wall and ditch, and contains many brick temples and pyramids. Cotton, canes, pepper, and tin are exported hence to China. Pop. about 5000.

LIGURIA, in *Ancient Geography*, a region of Northern Italy, stretching along the N. coast of the Tyrrhenian Sea. Considered in its primitive meaning as "the country of the Ligurians," it is mentioned by the early Greek authors as extending as far westward as the mouths of the Rhone; while, according to Polybius, its eastern boundary was Pisæ, and its northern the country of the Arretines. Strabo, however, and other ancient geographers, considered it as bounded on the N. by the Padus, on the W. by the Varus, and on the E. by the Trebia; and these same limits were fixed by Augustus, when he constituted Liguria the ninth region of Italy. The Ligurians were among the first settlers in Italy. Of their origin nothing certain is known, except that they were generally held by ancient writers to be distinct from the Celtic race, an opinion, however, which some moderns have opposed. The principal tribes on the S. side of the Apennines were the *Apuani*, the most formidable to the Romans; the *Brinates*; the *Genuates*, dwelling around Genua; the *Veturii*; the *Ingauni*, occupying the environs of *Albium Ingaunum*; the *Intemelii*; and the *Vediantii*. On the N. of the Apennines were the *Epanterii*; the *Eburates*; the *Taurini*, dwelling around their capital, *Augusta Taurinorum*; the *Statielli*, near *Aquæ Statiellæ*; and the *Vagienni*, in the neighbourhood of *Augusta Vagiennorum*. The distinctive positions of all these, as well as of the other inferior tribes mentioned by Pliny and Livy, have never been accurately defined. The following are the sea-coast towns enumerated by Pliny and Ptolemy:—*Nicæa* (Nice), *Cemenelum* (Cuniez), *Portus Herculis Monæci* (Monaco), *Albium Intemelium* (Vintimiglia), *Albium Ingaunum* (Albenga), *Vada Sabbata* (Vado), *Genua*, *Portus Delphini* (Porto Fino), *Tigullia* (Tregoso), *Segesta* (Sestri), *Portus Veneris*

(Porto Venere), and *Portus Lunæ*. The principal towns on the N. side of the Apennines, which latterly rose to great importance, and are styled by Pliny "nobilis oppida," were,—*Dertona* (Tortona), *Iria* (Voghera), *Asta* (Asti), *Pollentia* (Polenza), *Valentinum* (Valenza), *Augusta Vagiennorum* (Bene), *Alba Pompeia* (Alba), *Aquæ Statiellæ* (Acqui), *Augusta Taurinorum* (Turin), *Barderate*, *Industria*, *Carrea Potentia*, *Clastidium* (Casteggio), *Ceba* (Ceva), and *Libarra*. The Ligurians, so often praised by ancient authors for their hardihood and bravery, are generally understood to be those on the S. side of the Apennines exclusively. In the time of Strabo, these eked out the scanty produce of their stony and sterile soil by hunting and feeding flocks, and thus fostered that vigour of frame and ferocity of disposition which long rendered them the indomitable foes and plunderers of the Romans. They were renowned as slingers and light infantry in the armies of the Carthaginians, and afterwards in those of the Romans. The most remarkable natural product was a mineral resembling amber, called *λγγούριον*. Their chief export was timber, and their principal emporium Genua. For the physical geography of Liguria, see ITALY.

LIMFIORD, an extensive inlet of the North Sea, in the N. part of the Jutland of Denmark, between N. Lat. 56. 28. and 57. 8., and E. Long. 8. 12. and 10. 21. Area, about 250 square miles. It communicates with the Cattegat by its main entrance on the E., and with the ocean by a narrow passage on the W., opened in 1825 by the violence of the sea. In length from sea to sea it is 105 miles, and about 40 miles in maximum breadth. Its course is tortuous and broken by numerous islands, the largest of which is Mors, 15 miles long by 5 miles in breadth. The waters are very shallow, and the channels intricate; flat-bottomed boats, however, can navigate it with ease. The only entrance for vessels of any size is by the Cattegat inlet.

LILBURNE, JOHN, a famous demagogue, was born of an ancient family in the county of Durham in 1618. After receiving a scanty education, he was apprenticed to a clothier in London; and while in this humble station, his sympathy with the Puritanic party was so strong and intrepid that he became a confidant in all their enterprises. Repairing, at his own instance to Holland, he there printed Bastwick's *Merry Litany*, and during a sojourn of several months, and after his return to London, continued to publish vehement attacks upon the bishops and prerogative, which eventually, in 1637, brought him under the lash of the Star Chamber. After unflinchingly enduring 500 scourges and exposure on the pillory, he was thrown into the Fleet, and lay under a double load of irons until the meeting of the Long Parliament in 1640. During the civil war he fought valiantly, and was promoted by the Earl of Manchester to the rank of lieutenant-colonel; but offended at the rising prevalence of Presbyterianism, he exchanged the sword for the pen in 1645, and, amid repeated prosecutions and imprisonments, directed a ceaseless onset of pamphlets against the dominant party, which led to his banishment in 1650. In 1653, returning to England without a warrant, he underwent a trial; but upon giving security for good behaviour in the future, he was allowed to remain in the kingdom. He then became a preacher among the Quakers at Eltham in Kent, and died there in 1657.

LILLE, or LISLE, a strongly fortified and important manufacturing town of France, capital of the department of Nord, is situated on the Denle, a canal connecting the Scarpe and the Lys, 51 miles S.E. from Dunkerque, and 171 N. of Paris, by railway; N. Lat. 50. 38. 44., and E. Long. 3. 3. 59. It stands in a flat and fertile district, and is surrounded by very strong fortifications and wet ditches. It is entered by seven gates, has wide and regular streets, and is generally well built. One of the most conspicuous

Lilimford
||
Lille.

Lillebonne
||
Lillo.

objects in the town is a citadel in the form of a pentagon, attached to which there are barracks and magazines. This fortification is one of the finest specimens of the skill of Vauban, and is considered impregnable, both from being furnished with every description of military appliances, and because the canal can be used to isolate its position. The town-hall is a curious mass of buildings, in the Gothic style, built in 1430, and was anciently occupied by the dukes of Burgundy. It contains an interesting and valuable collection of drawings by the old masters, among which are 86 by Raphael, and 197 by Michael Angelo. The church of St Catherine, interesting for the beauty and simplicity of its architecture, is adorned with a painting by Rubens, considered by some the finest effort of his genius. The Hôpital Comtesse, founded in the thirteenth century, although somewhat injured by fire in 1467, is still in a good state of preservation. There are several buildings for scientific and literary purposes, an exchange, prisons, and a number of philanthropic institutions. Lille is very deficient in its supply of good water, and the greater part is taken from the canal.

The manufactures of Lille are very important, the principal being cotton yarn, cotton cloths of various kinds, woollen fabrics, paper, leather, soap, and oils. There are about 300 windmills in the neighbourhood, which are used in producing the oil. There are also sugar refineries, iron and copper foundries, and bleaching establishments. The trade in hops, chicory, hides, wool, &c., is extensive. The working classes, in consequence of low wages and dissipation, are always poor, and their dwellings are for the most part wretched ill-ventilated hovels.

Lille was founded in 1009, by Bandouin IV., Count of Flanders. It fell into the power of Philip the Fair, after a siege of three months, in 1297, and was taken again by Guy, Count of Flanders, in 1302. The Protestants attempted in vain to surprise it in 1581; and the French besieged it, without success, in 1645. Wrested from the Spaniards by Louis XIV., in 1667, and retaken by the allies in 1708, after a long and obstinate siege, it was ceded to France by the treaty of Utrecht. The Austrians bombarded it from the 29th September till the 6th October 1792, but the garrison, admirably supported by the bravery of the inhabitants, compelled them to raise the siege. On each side there was a loss of about 2000 men killed and wounded. Pop. (1851) 68,463.

LILLEBONNE (ancient *Juliobona*), a manufacturing town of France, department of Seine-Inferieure, situate at the foot of a wooded eminence on the Bolbec, an affluent of the Seine, 19 miles E. of Havre. Its appearance is dull and uninteresting, and most of the houses are constructed of wood. There are numerous cotton mills, and several tanneries in and around the town, and a brisk trade is carried on in leather, groceries, hardware, and cattle. In ancient times this was the chief town of the Caleti; and, as the remains testify, must have been one of the chief cities in Gallia Belgica. Traces of a Latin theatre exist close to the town. Near these remains is an old castle, once the residence of William the Conqueror, and where, it is said, he divulged to the assembled barons his scheme for the invasion of England. The only other building of mark is the parish church, surmounted by an elegant Gothic spire. Pop. 4300.

LILLO, GEORGE, a dramatist, was born in 1693, near Moorgate, in London, where he subsequently conducted a successful business as a jeweller. His first play, *Silvia*, produced in 1731, and written after the model of the *Beggar's Opera*, met with little success. Yet in the following year his tragedy of *George Barnwell* was acted at Drury Lane to crowded houses for twenty successive nights, and gained the notice of Queen Caroline, who requested to peruse the manuscript. His best tragedy, *Fatal Curiosity*,

produced at Haymarket Theatre in 1736, was attended with little success on its first appearance, but in the following year, through the friendly exertions of Henry Fielding, who was then manager, it was received with a fair amount of applause. About the same time was written his *Arden of Feversham*, modernized from an old tragedy of the same name. He died in 1739, shortly after finishing his tragedy of *Elmerick*. Leaving the high-bred sorrows and fancy-striking scenes of romantic tragedy, Lillo endeavoured to rivet the sympathies by the bare depicting of the woes and fatal passions of domestic life. His temporary success may be referred to the novelty of the plan, and (in his *Fatal Curiosity* especially) to the truthful description of the workings of human passion, and to the consummate art in the construction of the plot. The neglect into which this drama just named has fallen is a conclusive proof that the proper sphere of tragedy is amid scenes that afford at once a theme for poetry and a tale of pity,—that exalt the imagination while they affect the heart. His *Dramatic Works* were published, with an account of his life, by Thomas Davies, in 2 vols. 8vo, in 1775, and reprinted in 1811.

LILLY, JOHN, a dramatic poet, considered by some a reformer of the English language, was born in Kent about 1558. At sixteen he entered Magdalen College, Oxford, became Bachelor of Arts in 1573, and Master of Arts in 1575. After staying for some time at Cambridge, he repaired to London; and in 1579 was a dependant upon courtiers, and patronized by Queen Elizabeth. In 1580 was published his first work, *Euphues*, a romance, which, partly from its satire, and partly from its apophthegms and antitheses, gave popularity to an affected style of phraseology, called *Euphuism*. Lilly also published nine plays, six of which had been played before the Queen, and were afterwards published together in 1632. About 1589 appeared his pamphlet against Martin Marprelate, entitled *Pappe with a Hatchet*, which has sometimes been attributed to Nashe. The date of Lilly's death is unknown, but according to Anthony Wood, he was living in 1597, when his last comedy was published.

LILLY, William, the astrologer, was born at Diseworth, a village in Leicestershire, 1st May 1602. He was educated at the grammar-school of Ashby-de-la-Zouch; and went as an adventurer to London in 1620. There he was servant for some time to a mantua-maker; but in 1624 he became a domestic, and also clerk, to Mr Wright, master of the Salters' Company, in the Strand. Soon after his master's death, in 1627, Lilly married his widow, and receiving L.1000 as her dowry, he was released from the cares of any stated employment. After busying himself for some years in the interests of the Puritans, he began in 1632 to study astrology under Evans, a clergyman who had been expelled from his curacy for several frauds practised under the guise of his art. In 1633 he lost his first wife, and married a second with a dowry of L.500. He was employed in the following year to discover a treasure reported to be buried in Westminster Abbey, but while engaged at night in the presence of thirty others in poisoning his "Mosaical rods," a terrific storm arose, and scared the party. In 1644 appeared, for the first time, his almanac, entitled *Merlinus Anglicus Junior*, of which the first edition was sold in the course of a week, and which continued to be published annually for about 20 years. In the same year, three sons were seen on Prince Charles's birth-day; and Lilly, in 1645, publishing an interpretation of this phenomenon, under the title of the *Starry Messenger*, was charged before the Committee of Examinations with having, by certain passages in this book, incited the populace to insult the Commissioners of Excise, and burn the excise office. On its being proved, however, that these two offences had been committed previous to the publication of the *Messenger*, Lillo was acquitted. In 1647 Charles,

Lilly,
John
||
Lilly,
William.

Lilybæum whilst under guard at Hampton Court, sent a messenger to him to inquire in what part of the country he might safely lurk should he contrive to escape from his enemies. **Lillye.** Lilly recommended some part of Essex, about 20 miles from London; an advice which circumstances did not suffer to be tested. Not more effectual were the *aqua fortis* and the saw which he sent to the king in 1648, to aid his escape from Carisbrook Castle. About the same time some important information touching the affairs of France, which he received from the confessor to one of the French secretaries, was communicated to the Council of State as the fruit of his astrology, and was rewarded with L.50, and an order for a yearly pension of L.100. In 1654 his second wife died, and he married a third. In 1659 the King of Sweden, who had been praised in his Almanac of 1657, presented him with a gold chain and medal. At the Restoration, he was apprehended by order of parliament, but sued out his pardon under the great seal. During the plague of 1665, after all his attempts to recommend his art to the ministry had failed, he retired to Hersham, and practised as a physician under a license from Archbishop Sheldon. In 1666 he was consulted about the great fire, and though he claimed to have predicted it and the plague fifteen years before, confessed his ignorance of its cause. He died in 1681 of a dead palsy, bequeathing a considerable property to a tailor whom he had adopted, and was buried at Walton-upon-Thames, where a monument was erected over his grave by his friend Ashmole.

Among his works are:—*Christian Astrology*, 1647; *Monarchy or no Monarchy in England*; *Grebner's Prophecy*; *Passages on the Life and Death of King Charles*, London, 1651; *Annus Tenebrosus*, 1652, and *History of his Life and Times from 1602 to 1681; containing Observations upon the Life and Death of Charles I.*, London, 1715 and 1721, and published, with notes by Ashmole, London, 1774.

LILYBÆUM (modern *Marsala*), in *Ancient Geography*, a city of Sicily, was situate on a promontory of the same name, forming the most westerly point of the island, and distant from Africa about 90 geographical miles. It was built and fortified by the Carthaginians, for the reception of the inhabitants of Motya, when that city was sacked by Dionysius of Syracuse, in B.C. 397. Owing to its fortified strength, its safe harbour, and its proximity to Africa, it soon became the chief stronghold of Carthaginian power in Sicily; and, in B.C. 276, successfully withstood a siege of two months from Pyrrhus, after all the other cities of Sicily had been reduced. During the first Punic war it baffled the besieging Roman troops for more than nine years, till it was ceded, at the close of the struggle, in B.C. 241, according to the conditions of the treaty of peace. Though only a Roman provincial town, it continued prosperous; and, in the second and third Punic wars, and for many years after, it was often the mustering-ground for forces about to invade Africa. After the ruin of the Roman empire, it passed successively into the hands of the Goths, Vandals, and Arabians. Some portions of an aqueduct, coins, vases, and pieces of sculpture, are among the few remnants of the ancient city.

LILYE, or **LILY**, **WILLIAM**, the eminent grammarian, was born at Oldham, in Hampshire, about 1466, and at eighteen entered Oxford, as a demy of Magdalen College. After taking a degree in arts, he travelled towards the East, and, according to Wood, visited Jerusalem as a pilgrim. Attracted to Rhodes, by the number of eminent men who had fled thither after the capture of Constantinople, he spent five years there, engaged in the study of Greek. He then repaired to Rome, and studied the ancient languages under Sulpitius and Sabinus. On his return to England, in 1509, having instituted a school in London, he was the first Englishman who taught Greek in

this country. In 1510 he was appointed first master of St Paul's school, by Dr Colet, the founder. In this new sphere he laboured for twelve years, numbering among his pupils several who afterwards rose to eminence. He died of the plague in February 1523, and was buried in the north churchyard of St Paul's.

Of the *Brevissima Institutio seu Ratio Grammatices Cognoscenda*, London, 1513, which is commonly known by the name of *Lily's Grammar*, he wrote only the English Syntax, the Carmen de Moribus, the Rules for the Gender of Nouns, and the Rules for the Præterperfect Tenses and Supines of Verbs. The preface to the first edition was written by Cardinal Wolsey; the English Rudiments by Dr Colet; and the Latin Syntax chiefly by Erasmus. This grammar has gone through innumerable editions, the last of which is that of London 1817. His other principal works are:—*In Ænigmatica Bossi Antibossicon primum, secundum, tertium, ad G. Harmanum*, London, 1521; *De Octo Orationis partium Constructione Libellus*, 1540; *Institutio Compendaria totius Grammaticæ*, London, 1542; *Monita Pædagogica*, Glasgow, 1693. He also wrote Latin verses, and translations from Latin and Greek. He is styled, by his friend Erasmus, "no ordinary scholar in classical literature, and a master in the art of tuition."

LIMA, the capital of Peru, is situate on the banks of the Rimac, in S. Lat. 12. 2., and in W. Long. 77. 8. 30., distant 6 miles from Callao by railway. It stands on a large and arid plain, fertilized only by irrigation, and rising gradually from Callao, on the shores of the Pacific. The general appearance of the city is imposing, when viewed from a short distance, the spires and domes glitter gaily in the sun, and the rich Moorish architecture fills the traveller with admiration. But on a nearer inspection the effect is somewhat disappointing. For although the public buildings are handsome, and the streets distinguished by great regularity, most of the houses are low and irregularly built. The walls are composed of mud bricks, and the roofs chiefly of planks of wood, on rafters that are often curiously carved, above which is a cane-matting, and a thin coat of plaster or mud, sometimes overlaid with flat tiles, on which they have their gardens of flowers, and shrubs in pots, &c. The houses of the poor in the suburbs have flat cane roofs covered with cane-matting and mud plaster. A singular feature is the stream of water, intended to carry away all refuse from the streets and houses, which runs down the centre of those streets that pass lengthwise through the city. It is let on early in the morning, and at night is turned off into the fields and orchards. Lima is entered by six gates; and the principal Alameda, an avenue of great beauty on the Callao road, is one of the finest approaches. The Plaza Mayor, or great square, is adorned with a splendid fountain, and is one of the principal business localities. On the north side of the square is the ancient palace of the Spanish viceroy, but now of the president of Peru. The side of it which fronts the square is certainly not remarkable for its beauty, having a range of small shops, above which are several of the state offices. On the east side are the archbishop's palace and the fine cathedral. On the other two sides there is a range of colonnades, with commodious shops, and a tessellated pavement, over which are the long balconies of the houses supported by them. The town-hall (cabildo) is one of the buildings supported by the colonnades on the west side, and the old palace of Pizarro (which is entered from the Callejon of Petateros) is, on the south side, not to be distinguished outwardly in any way from the adjacent balconied dwellings of the inhabitants. Besides the Alameda, to which reference has been made, there are two others, one of which possesses an immense amphitheatre for bull-fighting, capable of accommodating not less than 16,000 spectators.

The churches and convents of Lima are very numerous

Lima.

Lima.

Second in importance to the cathedral, is the convent of San Francisco, an establishment which occupies a large extent of ground. The church of St Domingo has a magnificent tower about 180 feet high. These monastic establishments have been much reduced in number since the revolution. Those which remain, however, are rich in gold and jewellery. In 1821 an immense mass of silver was taken from them and devoted to the necessities of the state; and in 1853 they have been plundered of valuable pictures of the Spanish school. The total number of churches now remaining is 56; 5 of which are parish churches, and many of them are attached to convents.

Of educational establishments, we may especially instance the University of San Carlos; and the National Museum, which has an admirable library of about 26,000 volumes; and a separate department, well stocked with Peruvian antiquities. This institution was, at one time, the most important in S. America. There are also various colleges appropriated to theology, jurisprudence, and medicine; and, in connection with the latter of these, there is an indifferent botanic garden. The schools are numerous, and tolerably well managed. Of charitable institutions, there are at present three public hospitals for the sick; namely, Sant-Ana, for females; San Andres and San Bartolome for males; one for foundlings, and an asylum for penitent women; besides the hospital for incurables.

Commerce in Lima is often disturbed by revolutions, which interfere with the security of public property, and transit to and from the interior. One-half the whole imports of Peru is from Great Britain; and that to the extent of not less than four or five millions of dollars yearly. The manufactures are of slight importance, consisting chiefly of glass, gold lace, silver filigree, and gilded leather. Although the country in the vicinity is very productive, the indolence of the people is such that they do not improve their advantages. Grapes, water-melons, and a variety of grains and vegetables are produced in great abundance. Immense quantities of live stock are fattened in the neighbourhood; the number of pigs killed for consumption is said to be about 20,000 a-year; and from 300 to 400 sheep, and from 40 to 50 oxen are brought daily into the market. At the corners of some squares old women sit cooking fish and pork, which the lower orders purchase instead of preparing food for themselves at home. The foreign trade of Lima is transacted through its port, Callao; and, indeed, the most of the goods consumed are the produce of other countries.

Like their Spanish ancestors, the people are gay, fond of exciting amusements, and little addicted to intellectual or useful pursuits. Morality is lax among all ranks; and there is a great amount of gambling and other kinds of dissipation. The walking dress of the ladies is only to be met with in this city and in Truxillo. It consists of two parts, called the *saya* and the *manto*. The former of these is a tight-fitting, but elastic petticoat, so made that the form of the limbs is distinctly discernible. The *manto* is a thick veil made of crimped black silk, drawn in by a band behind, and fastened round the waist; but being drawn up over the head, it is made to conceal the greater part of the face, and often the whole of it except one eye. A rich coloured shawl or scarf is sometimes thrown over the shoulders under the *manto*, so as to hang down nearly to the feet. The tight *saya* has been of late rather giving place to a looser and more graceful garment of the same kind; and, indeed, the costumes of England and France, which have long been worn by the ladies when within doors, are now becoming common as walking dresses.

The climate of Lima is very agreeable, although, perhaps, somewhat enervating. In winter, the mean temperature is 64° 1', and in summer, 77° 6'. A light drizzly mist prevails between May and October, but rain seldom falls. Earthquakes are of frequent occurrence, but the more de-

structive ones take place at intervals of from fifty to sixty years. In October 1746 a great number of important public buildings and dwelling-houses were destroyed in Lima. The port of Callao was at the same time devastated by the sea; and out of a population of about 5000 inhabitants, only 200, according to Ulloa, escaped.

Lima was founded by Pizarro in 1535, and at that time received the name of Ciudad de los Reyes (the City of the Kings). Since 1537 it has been the capital city of Peru, and the seat of the viceroys. In the sixteenth century it became an archiepiscopal see. The population of Lima is stained with every variety of shade between black and white; and this medley of race is not at all improved by the recent introduction of Chinese to supply the place of the now liberated negro.

The number of inhabitants, at the outbreak of the revolution for independence in Upper Peru, in 1810, was estimated at upwards of 80,000; and in the work of Ledesma, one of the judges of the Superior Court in the capital, published in 1853, he also states the population of Lima as then above 80,000; and, including its sea-port of Callao, and watering-place of Chorrillos, the whole population may be estimated at 100,000. At the close of the war of independence the population of Lima was reduced to about 54,000; but again, during General Castilla's prosperous administration, the capital, which is about 10 English miles in circumference, was rapidly re-peopled from the provinces.

In 1854-55, the yellow fever entered for the first time, and carried off its thousands; while in the valleys of the interior, Cuzco, &c., upwards of 200,000 perished by this epidemic.

LIMBORCH, PHILIP VAN, a theologian of the Arminian or Remonstrant party, was born at Amsterdam, 19th June 1633. After receiving a good elementary education in his native city, he entered the University of Utrecht in 1652, and studied there for two years. In 1657 he became minister of a Remonstrant church in Gouda; and, in 1658, was transferred to Amsterdam, where, in the following year, he added to his pastoral duties those of professor of theology to his own sect. He died in 1712. Many eminent men in foreign countries, and, among others, Locke and Tillotson, were his correspondents. His most important works are:—*Præstantium ac eruditorum virorum Epistolæ Ecclesiasticæ et Theologicæ*, Amsterdam, 1660, 1684, and 1704; *Theologia Christiana*, Amsterdam, 1686 and 1730, containing a full exposition of the tenets of the Remonstrants; *De Veritate Religionis Christianæ*, Gouda, 1687; *Historia Inquisitionis*, Amsterdam, 1692, translated into English, with an introduction by Dr Samuel Chandler, London, 1731. An English translation of his *Theologia*, with improvements from Wilkins, Tillotson, Scott, and others, was published by W. Jones, in 2 volumes, London, 1702. Limborch also edited the works of his relative, Episcopius.

LIMBURG, or LIMBOURG, a former province of the Netherlands, now belonging partly to Holland and partly to Belgium; bounded N. by Gelderland, E. by Rhenish Prussia, S. by the province of Liege, W. by those of South Brabant and Antwerp, and N.W. by that of North Brabant; and lying between N. Lat. 50. 42. and 51. 47., and E. Long. 4. 57. and 6. 17. To Holland belong all those parts of the province E. of the Maese, with the town of Maestricht, and all N. of a line drawn north-westwards from that river near Stephanswerd to a point near Hamont; the rest, or south-western portion of the province, belongs to Belgium. The area of the whole amounts to 1784 square miles, of which 932 are contained in Belgian Limburg, and 852 in Dutch Limburg. The physical aspect and products of both portions are very similar. The surface is flat, and in the N. occupied by an extensive marsh called the Peel; while on the Belgian side a considerable tract is covered with

Limbroch
||
Limburg.

Lime moor and sandy plains. The River Maese traverses the province throughout its entire length, and receives several tributaries, the chief being the Roer, which joins it at Roermond, in the Dutch portion. Along the banks of that river the soil is well adapted to agricultural purposes, and produces grain of various kinds, flax, hemp, tobacco, rape seed, madder, and fruits. Extensive and well-stocked pasturages occupy the western parts of both Belgian and Dutch Limburg, but especially the former, where horse breeding and the tending of bees are carried on to some extent; while, among the Hollanders, pig rearing and the dairy receive more attention. In minerals the province is deficient. Some lime quarries are worked in the S., where also iron, calamine, and lead exist to a small extent; while coal, potters' earth, and building stone are found in the N. The manufactures are more important, and are about equally numerous in both parts. Among the Belgians the principal articles of manufacture are beet-root sugar, salt, tobacco, soap, and straw hats; besides which, the Dutch manufacture cotton, paper, glass, and gin. The following shows the area, arable acreage, and population of the province:—

Province.	Area.	Arable acreage.	Pop. 1850.	Pop. 1855.
Belgian Limburg ...	596,372	243,442	188,198	193,550
Dutch Limburg	545,006	352,259	205,261	210,831
Total	1,141,378	595,701	393,459	404,381

The history of this province is intimately connected with the foreign and civil wars of the Low Countries. It was a duchy, and formed one of the United Provinces under the rule of Charles V. of Spain. It was ceded to France by the Batavian republic in 1795, but afterwards was restored to the Netherlands. After the revolution of 1830, however, it was, according to the treaty of 1839, divided between Holland and Belgium; the former giving to its portion the title of Duchy. The capital of Dutch Limburg is Maestricht, with 27,000 inhabitants; and of Belgian Limburg, Hasselt, with a population of 10,000.

LIME. See CHEMISTRY (*Calcium*), and BUILDING.

LIMERICK, an inland county of the province of Munster, in Ireland, is bounded on the N. by the estuary of the Shannon (from which it derives the advantages of a maritime county) and Tipperary, on the E. by the same county, on the S. by the county of Cork, and on the W. by Kerry. According to the ordnance survey, it comprises an area of 1061 square miles, or 680,842 acres, of which 526,876 are arable, 121,101 uncultivated, 11,575 in plantations, 2759 in towns, and 18,531 under water. Of the 121,000 acres of uncultivated land, it has been estimated that 30,000 acres might be improved for cultivation, 40,000 acres might be drained for pasture, and 51,000 acres, situate chiefly on the high levels in the Galtees and Slieve Phelim Mountains, may be considered as unimprovable.

It was formerly inhabited by the tribe of the Velaborii. The principal Irish families in the county were the O'Briens, O'Grady's, O'Gormans, M'Enerys, M'Sheehys, Moronys, M'Mahons, and O'Quins. At the commencement of the thirteenth century, the Anglo-Norman proprietors, who had obtained grants of land, introduced colonists, chiefly from Bristol and Chester, into the rich lands about the city of Limerick and the northern part of the county. In 1586, the estates of the Earl of Desmond became forfeited, and those situate in this county, amounting to nearly 100,000 acres, were granted by the crown to Sir William Courtenay, Sir George Bouchier, Sir George Thornton, Sir Henry Uthered, Sir Henry Billingsley, Robert Annesley, William Carter, Edward Mannering, Robert Stroude, William Trenchard, Edward Berkeley, and Richard Fitton. Much of it

was confiscated in the time of Cromwell, since which period the proprietorship of the soil has mostly devolved upon settlers of English descent. The county is now divided into the fourteen baronies of Clanwilliam, Upper and Lower Connello, Coonagh, Coshlea, Coshma, Glenquin, Kenry, Kilmallock, North Liberties, Ownybeg, Pubblebrien, Shanid, and Small County, which are again subdivided into 131 parishes.

According to the ecclesiastical arrangements of the country, the county is in Limerick and Emly dioceses, and three or four parishes in those of Cashel and Killaloe. The see of Limerick is one of the few unaffected by the changes introduced into the ecclesiastical divisions of Ireland. It is still, as before, united with those of Ardfert and Aghadoc in Kerry. The cathedral, an ancient structure of considerable extent, but of no external beauty, stands in the city of Limerick; and the bishop's palace, a modern mansion, is situate on the bank of the Shannon, at the western extremity of the city. The chapter consists of a dean, precentor, chancellor, treasurer, and archdeacon, and has eleven prebendaries. The see of Emly, united with that of Cashel, has thirty-eight parishes in the county of Limerick, and twenty in Tipperary.

The face of the country, though diversified by numerous small hills, is not mountainous, except on the S.E., where it is bounded by the Galtees, the finest inland range of mountains in Ireland, which rise to an elevation of 3008 feet, and extend into the adjoining county of Tipperary. On the borders of Kerry the surface also rises into a grand amphitheatre of low but steep mountains, that spread themselves out in a wide curve from Loughlin to Dromcollogher. The Shannon forms the boundary of the greater portion of the northern part of the county, and is navigable for large vessels from Limerick to the sea. That portion of the river between Limerick and Killaloe (12 miles) is not navigable, on account of the rapids and shallows which occur. The River Shannon, which measures 240 miles in length from its source to the sea, has a total fall of 174 feet, 97 of which are within those 12 miles. The only river of any size is the Maig, which rises in the Galtees, and discharges itself into the Shannon, W. of Limerick. It is navigable by barges from the Shannon to the town of Adare. The Feale and the Gale, which rise in the western mountain range, are considered as belonging to Kerry, and the Blackwater, which rises in the same range, to Cork. The county is well watered by numerous smaller streams. There are no lakes of any importance in this county.

The soil in the level parts is considered as the richest in Ireland. Arthur Young said of this county and Tipperary: "It is the richest soil I ever saw, and such as is applicable to every wish. It will fatten the largest bullock, and at the same time do equally well for sheep, for tillage, for turnips, for wheat, for beans, and, in a word, for every crop and circumstance of profitable husbandry." The Golden Vale, a district which obtained its name from the remarkable exuberance of its fertility, lies mostly in this county. Along the banks of the Shannon are large tracts of marsh land, called Caucasses, also celebrated for their richness; a circumstance attributed to the quantity of alluvial mould deposited there by the Shannon when it overflows its banks. In a geological point of view the low country forms part of the great limestone plain of Ireland; but the mountainous district in the S. and W. consists chiefly of the old red sandstone, with clay-slate appearing in the loftier portions of the county. After leaving Lough Derg, the River Shannon passes through a gorge in this mountain range at Killaloe, and is precipitated down the rapids of Doonas and Castle-roy towards Limerick. At Castleconnel, a town beautifully situate, is a fine chalybeate spring, of great celebrity from its sanative effects.

The number of inhabitants at the following periods was:—

Limerick.

1760.....	De Burgho.....	92,376
1792.....	Beaufort.....	170,000
1821.....	Parliamentary return.....	277,477
1831.....	Ditto.....	315,355
1841.....	Ditto.....	330,029
1851.....	Ditto.....	262,136

The Irish language is understood by nearly thirty per cent. of the population, and upwards of 7000 cannot speak English. As regards the religious persuasion of the inhabitants, there are no accurate returns, but there can be no doubt that the Roman Catholics form at least nine-tenths of the population of this county.

The number of schools in the city and county of Limerick, and the children attending them, in the week ended 12th April 1851, was:—

CITY OF LIMERICK.	No. of Schools.	No. of Scholars.		
		Male.	Female.	Total.

Workhouse.....	19	2,814	2077	4,891
Total.....	274	10,253	8318	18,571

At the same period, in the city of Limerick, 37½ per cent., and in the county 51 per cent., of the population, five years old and upwards, are returned as being unable to read or write.

The county returned eight members to the Irish parliament: two for the county at large, two for the city of Limerick, and two for each of the boroughs of Askeaton and Kilmallock. The boroughs having been disfranchised at the Union, the number of representatives sent to the imperial parliament was fixed at three—two for the county, and one for the city. The Reform Act added one representative to the latter place.

The land in the level parts is divided into large farms, many of which are almost exclusively devoted to grazing. In the more hilly region the farms are smaller, and in some parts cut up into holdings much too small for the profitable culture of the soil, or the comfortable support of the cultivators. In the year 1709, a colony of Palatines, brought from Germany by Lord Southwell, settled near Bruff, Rathkeale, and Adare. They tended much to improve the state of agriculture, as also that of the linen manufacture. The rich lands on the borders of the rivers produce a kind of flax very different from that of the north; it grows to a great height, and is well adapted for sail-cloth. Hemp was formerly cultivated extensively on the lands of the same quality. The exportation of cattle and grain is very considerable, constituting the main source of the wealth of the inhabitants.

The extent of land under each description of crop in Limerick, 1854, 1855, and 1856, was:—

	1854. Acres.	1855. Acres.	1856. Acres.
Wheat.....	14,427	17,149	22,577
Oats.....	45,009	45,455	42,131
Barley, Bere, Rye, Beans, and Pease.....	15,343	12,057	7,537
Potatoes.....	33,282	35,723	43,428
Turnips.....	11,612	11,394	9,860
Other Green Crops.....	2,749	2,771	2,877
Flax.....	316	243	230
Meadow and Clover.....	69,117	71,292	72,330
Total.....	191,855	196,084	200,970

The quantity of live stock in the county in 1854-56 was as follows:—

	1854. No.	1855. No.	1856. No.
Horses.....	17,111	17,206	17,782
Cattle.....	158,874	159,710	160,421
Sheep.....	86,376	80,914	77,156
Pigs.....	69,214	61,733	50,346

The occupations of the people are almost exclusively agricultural. Their dwellings are poor, their food chiefly the potato; their fuel is turf, except in the immediate neighbourhood of the city, where British coal is much used.

The county possesses many remains of antiquity. The most remarkable of the ancient monastic buildings are in the city of Limerick, where, besides the cathedral, there was a Dominican friary founded by Carbreagh O'Brien, King of Thomond, in which he was interred. Some remains of the monument erected to his memory still exist. In the same city was an Augustinian friary, a convent of black nuns, a Franciscan friary, and a preceptory of knights-templars, besides several other minor religious establishments. Amongst the most admired of the many fine monastic ruins in various parts of the county is the Abbey of Adare.

The city of Limerick, the capital of the county, is situated on the Shannon, about 100 miles from its mouth, partly on an island, and partly on the mainland. It is the fourth city in Ireland in population and importance, being surpassed in these respects only by Dublin, Belfast, and Cork. The number of its inhabitants, in 1851, was 48,961. The city consists of three principal divisions,—the old town, divided into Irish and English Town; and Newtown Pery. The first is the most ancient, having been built before the arrival of the English in 1172. The second occupies King's Island, on the Shannon, and was formerly a strongly fortified position; both these portions consist chiefly of poor streets, and low village-like houses. The third was commenced in 1769, by Mr Sexton Pery, from whom it takes its name. It is laid out along the eastern banks of the river in streets, intersecting each other at right angles with geometrical precision, and contains many handsome streets of elegant houses, and squares, and public buildings of considerable pretensions. The city was formerly considered as the strongest place in Ireland. In 1174 it was taken by the English, but shortly afterwards evacuated and burned, to prevent its occupation being serviceable to the enemy. In 1651 it was taken by Ireton, Cromwell's lieutenant-general, after a vigorous resistance; and in 1690, its garrison baffled the army of King William, who conducted the siege in person; but it surrendered on terms the next year to General De Ginkel, on which occasion the celebrated treaty of Limerick was concluded. Most of the walls and gates have been demolished, and quays, warehouses, and streets, built on their site. The different parts of the town are connected with each other by bridges, of which the most remarkable, Thomond Bridge, leading from King John's Castle to Thomond Gate, has been lately rebuilt; and Wellesley Bridge, erected in 1827, one of the finest speci-

Limited
Liability
||
Limoges.

mens of this kind of architecture in the island. Besides the cathedral, and three parish churches, and two chapels of ease of the Established church, there are eight Roman Catholic places of worship. The Methodists, Presbyterians, Baptists, Independents, and Quakers have each a meeting-house. The chief public buildings are,—the court-house, the custom-house, the gaol, the commercial buildings, the lunatic asylum, the union workhouse, &c. The city was originally incorporated by King John, whose charter was confirmed and extended by several succeeding sovereigns. It was first governed by a bailiff, but obtained the privilege of electing mayors and sheriffs ten years before that right was conferred on London. The corporation, styled the "Mayor, Aldermen, and Burgesses of Limerick," now consists of 8 aldermen and 32 town-councillors. The charitable endowments are numerous, and some of them extensive. The manufacture of linen has been revived of late years; and Limerick is also celebrated for the manufacture of lace, gloves, and fishing-hooks. There are also several breweries, distilleries, tanneries, foundries, and flour-mills. The exports chiefly consist of provisions and grain. The imports are,—coal, turf, timber, wine, spirits, and all articles of British and foreign production. The navigation from the Atlantic to the city is open and secure, and the inland navigation connects it with Dublin and all the intermediate line of country. Vessels of 1000 tons can approach within five miles of the city, and those of 600 tons can unload at its quays. The harbour extends about 1600 yards in length, and 150 in breadth, with from 2 to 9 feet at low water, and 19 at spring tides. In 1835 the exports were valued at L.726,430, and in 1842, at L.1,200,000. The number of vessels entered inwards, in 1855, was 601, of 83,585 tons. Eleven vessels, of about 1760 tons in all, belonged to Limerick shipowners in 1832. In 1855, 88 vessels, of 12,090 tons, were registered as belonging to the port.

The other towns of some note in the county are,—Rathkeale, Shanagolden, Ballingarry, Newcastle, Adare, Askeaton, and Castleconnell. Kilmallock is more remarkable for its remaining vestiges of former greatness than for its present condition. It was the second town in the county, having a charter of incorporation, being surrounded by substantial fortifications, and consisting of a number of large houses, durably constructed of cut stone, and belonging to the age of Elizabeth and James I. (H. S.—R.)

LIMITED LIABILITY. See PARTNERSHIP.

LIMOGES (ancient *Augustoritum Lemovicum*), a town of Central France, formerly capital of the province of Limousin, now of the department of Haute-Vienne, on the right bank of the Vienne River, here crossed by three bridges, 115 miles N.E. of Bordeaux; N. Lat. 45. 49. 52., E. Long. 1. 15. 36. It is situated on an acclivity, which rises from the water side; the older parts of the town occupying the ground near the river, while the new town stretches over the summit of the hill. The streets of the former are narrow and tortuous, with mostly timber-built houses; but the modern portion has been elegantly laid out in regular streets and squares, with public fountains. In place of the old fortifications, boulevards now encircle the town, which is also adorned by many interesting edifices. The chief building, the cathedral of St Etienne, was begun in the thirteenth, and received additions up to the sixteenth century, when it was left still unfinished. It is of granite, and in the Gothic style of architecture, but is much mutilated; and, with the exception of bas-reliefs representing the labours of Hercules, and the tomb of Bishop Langeac, contains nothing worthy of notice. The church of St Michel-aux-Lions, erected in the fourteenth century, occupies the highest site in Limoges, and is rendered still more prominent by its spire and tower, which rise far above all the adjacent buildings. Among the other remarkable edifices

VOL. XIII.

Limousin
||
Linacre.

are the episcopal palace, a handsome structure built of granite; and the church of St Aurelian, with a very elaborately carved cross in front. The town also contains a college, a public library, with 12,000 volumes, a school of medicine, and several hospitals. It is the see of a bishop, and has courts of appeal, tribunals of first instance and commerce, and a council of *prud'hommes*. The trade of the place is important, and embraces principally the products and requirements of the surrounding country. It has likewise a large trade with the southern departments of France in grain, wine, brandy, liqueurs, and chestnuts; besides salt, iron, tin, and enamel. Kaolin clay, which abounds in the vicinity, is made here into excellent porcelain, and is also sent as raw material in large quantities to Sèvres. Cloth, worsted, woollens, paper, crucibles, and papier-mâché are the other chief articles of manufacture. A large monthly cattle-market is held here, and nine annual fairs.

In ancient times Limoges was the chief city of the Lemovices, and was much enlarged and improved under the Romans; a theatre, a citadel, and temples were erected, of which no remains are now extant. At the fall of the Roman empire, however, it was pillaged by the Vandals and Visigoths, and was afterwards taken in succession by the Franks and Normans. In modern times it has suffered much from sieges. Having revolted from the Plantagenets, it was besieged by Edward the Black Prince in 1370, taken by assault, and its inhabitants delivered over to the English soldiers, who treated them with great barbarity. It was recovered by the French two years after. The town was the birthplace of many great men, of whom the chief are,—Pope Clement VI., the Chancellor d'Aguesseau, Vergniaud the republican orator, Marshal Jourdan, and Cruveilhier the physician. Pop. (1851) 37,010.

LIMOUSIN, or LIMOSIN, a former province of Central France, now represented by the department of Corrèze and the greater part of that of Haute-Vienne.

LIMOUX, a town of France, capital of a cognominal arrondissement, department of Aude, 18 miles S.S.W. of Carcassone. It is pleasantly situate in a fertile valley of the N. Pyrenees, on both sides of the Aude, and is surrounded with vineyards, where the celebrated Blanquette and Limoux wines are made. The town is well laid out, and possesses several public fountains. There are also a college, a theatre, an hospital, and tribunals of first instance and of commerce. The manufactures of the place comprise broadcloths, woollens, soap, leather, and oil; and a brisk trade in wines and iron is carried on. Pop. (1851) 7188.

LINACRE, THOMAS, a learned physician, was born about 1460, at Canterbury, and educated there under the accomplished William Selling. After studying at Oxford, and becoming fellow of All-Souls' College in 1484, he set out for Italy with his former instructor Selling, who had been appointed ambassador from Henry VII. to the court of Rome. Settling down at Florence, he was permitted by Lorenzo de' Medici to attend his sons' preceptors, and progressed rapidly in Greek under Chalcondylas, and in Latin under Angelo Poliziano. He then removed to Rome, where, applying himself to the study of natural philosophy and physic, he became more intimate with Aristotle and Galen in the original than any Englishman before him. On his return to England he received the degree of M.D., and the appointment of public professor of physic from the University of Oxford; but was called to court by Henry VII. to be physician and tutor to Prince Arthur. He was afterwards successively physician to Henry VII., Henry VIII., and the Princess Mary. In the reign of Henry VIII. he founded two lectures on physic at Oxford and one at Cambridge; and in 1518, chiefly through his influence, letters-patent were issued for the foundation of the College of Physicians in London, vesting in that body the right of examining all medical practitioners in the capital,

Linacres
||
Lincoln.

and within 7 miles around it, and of licensing all physicians throughout the rest of the kingdom who were not graduates of Oxford and Cambridge. Of this college Linacre was the first president, and held that office till his death. Having commenced to study divinity late in life, he was presented in 1509 to the rectory of Mersham, a benefice which he exchanged in the same year for a prebend in the church of Wells. In 1518 he became a prebendary, and in 1519 precentor in the Church of York. Resigning the latter office, he obtained more preferments, and, among others, a prebend in St Stephen's Chapel, Westminster, and the rectory of Wigan, in Lancashire. He died under a severe attack of the stone, on the 20th of October 1524, and was buried in St Paul's Cathedral. Thirty years afterwards, a monument was erected over his grave by Dr Caius.

Linacre was esteemed in his own day, not less for his private virtues than for his unrivalled skill as a physician. His character as a scholar is established on the high authority of Erasmus, who says, "that his translations of Galen speak better Latin than before they ever spoke Greek." As a restorer of classical learning in England, he ranks with Colet, Lily, Grocyn, and William Latimer.

His translations from Galen are,—*De Temperamentis*, Cambr. 1521; *De tuenda Sanitate*, Cambr. 1517, Paris, 1530; *De Methodo Medendi*, Paris, 1526; *De Naturalibus Facultatibus*, London, 1523 and 1723; *De Pulsuum Usu*, London, 1522; *De Symptomatum Differentiis unus liber*; *Ejusdem de Symptomatum Causis libri tres*, London, 1524. His other works are,—A translation of *Proclus de Sphæra*, printed in the *Astronomi Veteres* of 1499; *De Emendata Structura Latini Sermonis libri sex*, London, 1524, frequently reprinted; *The Rudiments of Grammar*, written for the use of the Princess Mary, and translated into Latin by George Buchanan. In conjunction with Grocyn and Latimer, he began a translation of Aristotle, which was never finished.

LINARES, a town of Spain, province of Jaen, on a plain near the right bank of the Guadalimar, and under the Sierra Morena, 23 miles N.N.E. of Jaen. It has long been celebrated for its mines of lead and copper, which are still very productive. Near it was won Scipio's great victory over Hannibal; and the chief fountain of the town is supposed to be of Roman origin. Pop. about 7000.

LINCOLN, an ancient city of England, capital of the county of that name, 132 miles N.W. from London. It is situate on the summit and declivity of a considerable and very steep eminence which rises on the N. side of the River Witham at its confluence with the Foss Dyke Canal. Lincoln occupies the site of the Roman Station *Lindum*, the form of which may still be clearly traced; and one of the most interesting objects in the city is the ancient Roman archway called Newport Gate, which formed the barrier on the north side of the city. The town, as a whole, is not well built; and the streets leading from the lower to the upper town are too steep to be ascended by carriages, which make use of another road round the face of the hill without the city. The chief attraction of Lincoln is its cathedral, which stands on the very summit of the hill, and thus, both from its situation and its stately and towering grandeur, forms a conspicuous and magnificent object. It was founded in 1086, but was rebuilt subsequently to a fire in 1126, by which the greater part of it was destroyed. Its form is that of a very long double cross, with a transverse limb at the west end, like a pedestal made by the unusual breadth of the west front. There are two towers at the western front, each 180 feet high, and one great central tower 300 feet in height. Its interior dimensions are,—entire length, 482 feet; width of choir and nave, 80 feet; height of ditto, 80 feet; width of west front, 174 feet; length of principal transepts, 222 feet; breadth of ditto, 66 feet. The west front, two circular windows, the choir and screen, and the Lady Chapel, are

Lincoln-
shire.

peculiarly beautiful and interesting. The celebrated bell, the Great Tom of Lincoln, cast in 1610, was cracked in 1827, and broken up in 1834 to form, with six others, the present large bell, and two quarter bells, now in the central tower. It is 6 feet 10½ inches in diameter at the mouth, and weighs 5 tons 8 cwt.,—nearly a ton more than the old bell. On the north side of the cathedral are the cloisters, in which is preserved a Roman pavement. The library contains some curious specimens of Roman antiquities. In the cathedral are numerous monuments, including those of Catherine Swinford, wife of John of Gaunt, their daughter Joan, Countess of Westmoreland, and several bishops and deans of the cathedral; but many of the older monuments have been removed, or were totally destroyed during the civil wars. The other buildings worthy of notice are the chapter house, the ruins of the bishop's palace, destroyed during the civil wars, the remains of the castle, with the county jail and court-house, guild-hall, city jail, assembly rooms, theatre, &c. The city abounds in antiquities, and especially in monastic and other ecclesiastical remains. There are thirteen other churches of the Establishment (only about one-fourth of the numbers said to be standing at the Reformation), besides various dissenting places of worship. There are also a free grammar school, mechanics' institute, mutual improvement society, libraries, museum, county hospital, dispensary, lunatic asylum, &c. The markets of Lincoln have, within the last few years, been greatly enlarged and improved. It carries on a large trade in flour by means of the Foss Dyke Canal, connecting the Witham and Trent, and the railways which connect it with all parts of the kingdom. There are several large steam flour mills and several breweries in the town. Lincoln at the time of the Norman Conquest was one of the most important places in the kingdom. William the Conqueror caused a strong castle to be erected here in 1086. King Stephen was defeated and taken prisoner here in 1141 by Robert, Earl of Gloucester, natural brother to the Empress Maud. Lincoln was the scene of important operations during the civil wars in the reign of King John; and here the party of the Dauphin was completely overthrown by the Earl of Pembroke, during the minority of Henry, III. During the great civil war, the royalists obtained possession of the city, but it was stormed by the parliamentary army under the Earl of Manchester, 5th May 1644. Lincoln is governed by a mayor, 6 aldermen, and 18 councillors, and returns two members to parliament. Pop. (1851) 17,536.

LINCOLNSHIRE, a maritime county of England, on the E. coast, bounded N. by the estuary of the Humber, N.W. by Yorkshire, W. by the Trent and Nottinghamshire, S.W. by the counties of Leicester and Rutland, S. by those of Northampton and Cambridge, and E. by the North Sea. It is 73 miles in length from N. to S., by 46 miles in breadth; and contains an area of 2776 square miles, or 1,776,738 acres, being the second largest county in England. The shire is divided into three trithings or districts, viz.,—Lindsey, Kesteven, and Holland. The first is by far the largest division, and includes the whole of N. Lincolnshire; its boundary line reaching as far S. as the Foss Dyke and River Witham; following the course of the latter to a point opposite Thornton-le-Fen, where it crosses the country to the sea near Friskney. Kesteven trithing, on the other hand, comprehends the S.W. part of the county, while Holland occupies the flat lands of the Wash. These divisions are again subdivided into wapentakes, soles, and hundreds; amounting, in all, to thirty "parts."

The aggregate population of the whole county was, in 1821, 283,058; in 1831, 317,465; in 1841, 362,602; and in 1851, 407,222. The numbers of males and females in 1851 were,—males, 205,083; females, 202,139; showing a marked deficiency in the latter. Of towns containing

Lincoln-
shire.

more than 5000 inhabitants, in 1851, in this county, there were eight, viz.,—Lincoln, with 17,536; Boston, 17,518; Great Grimsby, 12,263; Grantham, 10,813; Louth, 10,467; Stamford, 8933; Spalding, 7627; Gainsborough, 7506.

In relation to the character of its surface, Lincolnshire may again be divided into three parts—the Wolds, the Heaths, and the Fens; which occupy positions corresponding generally with the three territorial divisions mentioned above. The Wolds are chalk downs which traverse the N. part of the county, from Barton to Burgh, in a S.E. direction for nearly 50 miles, and have an average breadth of 6 miles. They form the back-bone of the geological formation of the shire; and are skirted on the W. by a band of green-sand and one of iron-sand, which form another range of uplands running almost parallel with the Wolds. The Heaths occupy the land W. of the Wolds, stretching N. and S. from the Humber to Grantham. Their formation belongs to the Oxford clay, and widens in extent as it proceeds southwards until it ultimately dips under the fen land near the last-named town. The north-western corner of the shire is occupied by Permian strata, which follow the Trent into Nottingham, and westwards into York. Gypsum is found in the Isle of Axholme. The Fens cover the rest of Lincolnshire, from Wainfleet in the N., to the southern boundaries of the county, occupying the greater part of the district called Holland. They are intersected in every direction by drains, some of which are navigable; and the soil is now very productive. (See BEDFORD LEVEL.)

The principal rivers in the county are the Trent, Witham, Ancholme, Welland, and Nene, with their tributaries. The first enters Lincolnshire from Notts, a little above Rampton, when it becomes the boundary between the two shires, and continues to be so until it receives, on the left, the waters of the Idle. About a mile below its junction with that stream, the Trent leaves Nottingham, and flows in a northerly course through Lincolnshire for nearly 20 miles, when it falls into the Humber, by a mouth a mile in width. The Trent becomes navigable for vessels drawing 12 feet of water at Gainsborough; whilst its waters are affected by the tide for some miles above that town. It forms the eastern boundary of the Isle of Axholme, which is inclosed on the S. by the Idle, and on the W. by the old River Don. The former stream is navigable for small craft as far up as E. Retford. Although not so large as the Trent, the Witham is the most important river of Lincolnshire. It rises in Rutland, enters Lincoln near S. Witham, and flows northwards through a comparatively high valley to Grantham. From this it continues, for a short distance, its northern course, then turns to the W.; and again, at Long Bennington, changes to N.E., in which direction it flows to the town of Lincoln, where it receives the Brant on the left. Here the river becomes navigable for barges, and is connected with the Trent by the Foss Dyke Canal. Here, also, it enters on the flat lands, flowing first E. as far as Bardney, where the Langworth and S. Beck are received on the left; then, turning gradually to the S.E., reaches Tattershall, where it is joined on the right by the Sleaford, and on the left by the Bain. From Tattershall to Boston the Witham occupies an artificial bed; but from the latter town to the Wash it keeps its natural course. Vessels of 300 tons can ascend to Boston. North Lincolnshire is drained by the Ancholme, which rises near Spirdlington, flows northwards till it enters the Humber, near Ferraby, and is navigable for about 20 miles. The Welland enters South Lincolnshire at Stamford, where it is navigable, and keeps an eastern course to Market Deeping. Six miles therefrom it penetrates the county of Lincoln; and, after receiving the Glen near its mouth, enters the Wash. Connected with all these rivers, there are extensive drainage and canal systems, which have, in some cases, taken the place of the natural courses of the

streams. In the trithing of Holland, especially, draining has been carried on so universally, that it is difficult to discover whether the streams are natural or conducted by the hand of man. This system, indeed, has rendered the soil of this part of Lincolnshire one of the most productive in England, when, formerly, it was little better than moor or bog.

The climate of the shire is as good as in most of the other English counties, except in those flat lands that have not been thoroughly drained, where cases of ague are not unfrequent among the inhabitants. The soil is varied, but generally very rich. In the Fens it produces excellent pasture, and in some parts extraordinary crops of grain, particularly oats. Here, however, the water is bad; and still considerable tracts of land are fit for no more profitable purpose than the breeding and rearing of geese. These are kept principally for the sake of their quills and feathers, which are plucked four or five times in the year. During breeding season they are lodged in wicker pens, closely attended by a herd. The Fens were long the resort of vast flocks of wild fowl, the entrapping of which formed an important branch of employment to the inhabitants; but of late years their numbers have been so reduced that they now only engage the attention of the sportsman. The aquatic birds which still frequent the marshy portions of Holland are chiefly swans, wild geese, mallards, shovellers, godwits, and occasionally spoonbills. Agriculture is conducted with considerable skill and judgment in this county; and the land produces ample crops of wheat, oats, barley, and beans, and in some parts hemp and flax. In the Wolds, where the soil is chalky, sainfoin is sometimes grown besides the usual crops; while cabbages and carrots are found to succeed well in those parts of the W. and S.E. of the county where the soil is found most suited for their production. Wherever the soil is apt to grow thin, the farmers here are in the habit of making the streams or "cuts" overflow their banks, and thus deposit a layer of rich silt on which beans, oats, and woad are produced. But however well adapted some parts of Lincolnshire are to the growing of grain, it is undoubtedly on the whole a pastoral county, as it has perhaps the richest grass grown in the kingdom. Breeding and rearing of cattle, sheep, and horses, for the London market, form the main pursuits of the population. The two original breeds of cattle in the county were the Lincolnshire short-horned, and Leicestershire long-horned; but these have been much improved by frequent and judicious crossings, and the oxen of Lincolnshire are now proverbial for their excellence. There are also many cattle from other parts fattened here for the metropolitan market. Of sheep, the principal breeds are the native Lincoln and New Leicester. The former are of large size, and produce heavy fleeces of long wool. Their flesh, however, has a rankish flavour, and is not generally relished. The New Leicester, on the other hand, obtained by crossing the native race with other breeds, has now become more numerous, and is highly prized. The total number of sheep in the county has been estimated at two millions and a half, and the yearly produce of wool at twenty million pounds. Lincolnshire has also been long famous for its breed of horses, including drays, hunters, and carriage horses. They are generally reared on the uplands, but afterwards removed to the "flats," to get flesh before being sent to Horncastle, the great horse market of the shire. Some good breeds of swine are to be found in the county, but less attention has been directed to them than to cattle. Stilton cheese is made here, but there are few large dairies, as most of the farmers keep milk cows only for domestic use. Manufacture is almost wholly wanting in Lincolnshire, and trade is consequently confined to natural produce, such as grain, cattle, wool, and feathers. In minerals it is likewise deficient, with the exception of excellent freestone, quarried near Ancaster, in Kesteven; sul-

Lincoln-
shire.

Lincoln-
shire.

phate of lime, found in the Isle of Axholme; and some lime burnt in the Wolds. Means of communication are, however, abundant both by rail and canal, as well as by the sea coast. The Great Northern Railroad crosses the S.W. corner of the county through Grantham, and sends a branch along its eastern border by Spalding, Boston, Alford, and Louth to Great Grimsby, with a sub-branch from Boston to Lincoln. From the Midland Railway at Nottingham a line goes to Lincoln, and thence, by Market-Rasen, to Blanford Brigg; while the Manchester and Sheffield line sends a branch by Gainsborough to the same place, and then northwards to New Holland, and southwards to Great Grimsby. Canals are still more numerous; in fact, no county in the United Kingdom is so well supplied with such channels of communication. The principal ones are the Foss Dyke, connecting the Trent and Witham; the Car Dyke, connecting the Welland and Witham; the Stainforth and Keadley Canal, connecting the Don and Trent, across the Isle of Axholme; the Louth Canal, running between that town and the Humber; the Sleaford Navigation, communicating with the Witham; and the Grantham and Nottingham Canal. The sea coasts of Lincolnshire are not, however, favourable for navigation. From the Wash to the Firth of Humber, the shore is low and lined with sandbanks, except near Grimsby, where it rises into cliffs. In the basin of the Wash are many sandbanks which become dry at low water; the greatest depth of water is at Boston Deep, where it averages from 3 to 8 fathoms. A sea-wall extends also along the coast of this estuary from the Welland to the Nene, to protect the land from the encroachments of the sea. There are three chief seaports in Lincolnshire,—New Holland, on the Humber, opposite Hull; Great Grimsby, at the mouth of the Humber, carrying on a pretty extensive foreign trade; and Boston, on the Witham, 6 miles from the sea, which exports the produce of the county, and imports from the Baltic. Gainsborough, situate on the Trent, 21 miles from the Humber, has also a considerable export and import trade; vessels of 300 tons being able to ascend to the town.

Lincolnshire returns 13 members to parliament,—2 from Lindsey, or North Lincoln; 2 from Kesteven and Holland, or South Lincoln; and 9 from the boroughs of Lincoln (2), Boston (2), Grantham (2), Stamford (2), and Great Grimsby (1). The place of election for North Lincoln is Lincoln, and for South Lincoln, Sleaford. This county also belongs to the Midland Circuit; and the assizes are held in Lincoln, where the county jail is situate; while the quarter sessions are held throughout the county. According to the Poor Law Commission, the shire is divided into the 14 unions of Boston, Bourne, Caistor, Gainsborough, Glanford-Brigg, Grantham, Holbeach, Horncastle, Lincoln, South Sleaford, Spalding, Spilsby, and Stamford. Ecclesiastically, the county belongs to the diocese of Lincoln and province of Canterbury. In 1851 there were 1501 churches in the shire, with 281,266 sittings. Of the former, 657 belonged to the Established Church, 703 to the Methodists, 62 to the Baptists, 38 to the Independents, and 13 to the Roman Catholics. There were also in that year 1420 day schools in the county, with an aggregate of 52,163 scholars; 457 of the former being public, with 32,267 scholars; and 963 private, with 19,896 scholars. Of Sunday-schools in the same year, there were 880, with an aggregate of 57,120 scholars. 432 of these belonged to the Established Church, and 318 to the Methodists. There were also 23 literary and scientific institutions, with an aggregate of 22,654 volumes in their libraries, and an average of 120 members to each association. The principal mansion-houses in the county are,—Aswarby Hall, Whichcote, Bart.; Belton Park, Earl Brounlow; Blankney Hall, C. Chaplin, Esq.; Brocklesby Park, Earl Yarborough; Buckminster, Lord Huntingtower; Burton Hall, Lord Monson; Casewick Hall, Sir J. Trollope,

Lincoln-
shire.

Bart.; Coleby Hall, Sir C. Tempest, Bart.; Glentworth Earl Scarborough; Grimsthorpe Castle, Lord Willoughby d'Eresby; Hainton Park, G. F. Heneage, Esq.; Harlaxton House, G. Gregory, Esq.; Haverholme Priory, Earl Winchelsea; Nocton Park, Earl Ripon; Normanby Hall, Sir R. Sheffield, Knt.; Redbourne, Duke of St Albans; Revesby Abbey, J. B. Stanhope, Esq.; Riseholme Palace, Bishop of Lincoln; Somerly Hall, Sir T. Beckett, Bart.; Stubton Hall, G. Nevile, Esq.; Thurby Hall, Sir E. G. Bromhead, Bart.; Uffington Hall, Earl Lindsey. When the Romans conquered Britain, Lincolnshire seems to have been occupied by the Coritavi, or Coritani, who are mentioned by Ptolemy as having *Lindum* and *Rhage* (Lincoln and Leicester) for their chief towns. After the subjugation of the county, Lincolnshire formed part of the province of *Flavia Cæsariensis*, a division the boundaries of which are given only on the questionable authority of Rufus Festus, but which seems to have comprised all the midland and eastern counties of England. Ermine Street, with its two branches, the Fossey and Upper Saltway, was the road by which the Romans kept up their communications through the province. The Upper Saltway communicated between the salt works of Worcestershire and the coast. *Lindum* (Lincoln), *Causennæ* (probably Ancaster), *Ad Abum* (probably near Winterton), were the principal Roman stations; and hypocausts, sarcophagi, urns, altars, coins, and tessellated pavements have been found as traces of the Roman occupancy. At Scampton, a Roman villa of very large size was traced in massive and well-preserved foundations. Two camps, undoubtedly Roman, existed at Gainsborough and Aukborough, with well-defined characteristics, as late as the beginning of the present century; and two others near Holbeach and Grantham are known, but their antiquity is not so certain. The Saxon province of Lindsey did not embrace the whole of Lincolnshire; but we find the Saxon *Lindo-Collyne* as the name of the capital, a word which easily slid into the *Nichol* of the Normans, when they gained possession of the county about the year 880. Lincolnshire after this formed part of the *Danelag*, or territory ceded to the Danes, and ultimately came under the Anglo-Saxon crown. In the civil wars the most memorable events are the siege of Lincoln (1141), and the insurrection of Sir Robert Wells against Edward IV. At the Reformation an attempt was made to resist the suppression of the monasteries, but it was soon defeated. In the parliamentary wars Lincolnshire was the scene of several actions. Charles I. captured Grantham in 1642; and the parliamentary forces were victorious at Grantham, Ancaster, Gainsborough, and Horncastle in that same year.

The antiquities of Lincolnshire are numerous. Almost all the churches are fine specimens of ancient architecture; and it is somewhat remarkable that the most beautiful edifices are to be found in the lowest and most fenny situations, when, at the time of their erection, the means of communication must have been very limited; yet, under these disadvantages, were built the churches of Boston, Pinchbeck, Spalding, Holbeach, and other places. The ecclesiastical buildings in the division of Lindsey, with the exception of Lincoln Cathedral, are generally inferior to those in Kesteven and Holland; but Barton-upon-Humber, in that division, contains one of the only two churches in England which are considered to be of undoubted Saxon origin.

The other most interesting antiquities, besides the Roman and other remains in Lincoln itself, are Crowland Abbey, which was founded in 716, and was formerly a place of great importance. Near it is the old triangular bridge, which is supposed to have been built about 860, and has been stated to be the oldest bridge in England. Torksey Castle, at the junction of the Foss Dyke with the Trent; Thornton Abbey, near the Humber, founded about

Lindan
||
Lindsay.

the year 1139; Whykham Chapel, near Spalding, built about 1292; Bardney Abbey, on the banks of the Witham; Tattershall Castle, on the same river, erected about 1440; and Somerton Castle, in the parish of Boothby.

Sir Isaac Newton, Lord Burghley, Lord Bolingbroke, Stukely the antiquarian, Wesley the founder of Methodism, and Fox, the author of the *Book of Martyrs*, were, amongst many other eminent men, natives of this county.

LINDAU, a town of Bavaria, circle of Swabia, situate on three islands in Lake Constance, 100 miles W.S.W. of Munich. It is united with the mainland by a long wooden bridge. It was formerly fortified, but its ramparts have disappeared, and their place is now occupied by flower-gardens. The town contains a castle and four churches, and carries on a brisk trade in grain and wine with Switzerland and Italy. Steamers ply from its harbour to the other lake ports daily. The Romans under Tiberius are believed to have constructed a fortress here, and some remains of an ancient wall and tower are supposed to be a part of it. Pop. about 3500.

LINDSAY, or LYNSAY, SIR DAVID, a Scottish poet, descended from a younger branch of the family of Lord Lindsay of Byres, was the eldest son of Lindsay of Garmylton, in the county of Haddington, and of the Mount, in the county of Fife. He was born in Fife at some period before 1500, and, according to the ordinary opinion, studied at St Andrews from 1505 till at least 1508. How he was employed for several years after this period is uncertain; but in 1512 he became an attendant upon the infant prince, afterwards James V., and, according to Buchanan, in his *History*, was also "special servant" to the king. His wife, Janet Douglas, had for many years charge of the king's linen. In 1524 he was removed from his post, as an obstacle to the ambitious projects of the Earl of Arran, who had married the queen dowager. His pension, however, was continued. Impatient under his absence from court, he published in 1529 his *Complaynt*, in which he feelingly reminds the king of his gentle and devoted services to him when a child. No sooner had James secured, in 1530, the full regal power, than he conferred upon Lindsay the office of Lyon King-at-Arms, and soon afterwards the honour of knighthood. In his new capacity, he was sent with two others, in 1531, on an embassy to Charles V. touching the commerce between Scotland and the Netherlands. He was one of the ambassadors that bore proposals of marriage from the king, first in 1535, to a princess of the imperial family, and in the following year to a daughter of the Duke of Vendôme; but in both cases without success. James married Magdalene of France in July 1537; and in two months after Lindsay wrote his poem entitled, *The Deplo-ration of the Deith of Quene Magdalene*. After the king's death in 1542 he supported the regency of the Earl of Arran as long as it was favourable to church reformation. In 1543, and the two succeeding years, he represented in parliament the burgh of Cupar; and in 1544 he was sent on an embassy to the emperor to deliver the insignia and the statutes of the order of the Golden Fleece, which had been conferred on the late king. Four years afterwards he was an ambassador at Copenhagen. At an early stage of his career Lindsay had incurred the hatred of the priesthood, by lashing with his piquant satire their avarice, profligacy, licentiousness, and absurd religious ceremonies, but had been shielded from their persecution by the favour of James V. Soon after the murder of Cardinal Beaton in 1544, he was forced to take refuge, along with other reformers, in the castle of St Andrews; and, in 1547, was one of those who urged Knox to receive ordination. In 1548, by his mission to Denmark, he secured free trade in grain with that country for Scottish merchants. He is supposed to have passed his latter years in retirement, and to have died at some period between 1555 and 1558.

Lindsey.

A poet, in the highest sense of the term, Lindsay certainly was not. His claim to notice is chiefly derived from his stinging satire, and his intrepid exposure of ecclesiastical disorders, the two weapons that he wielded so effectively in the battle of the Reformation. His vivacity, his manly common sense, and his true and humorous delineations of manners, long rendered him a favourite with his countrymen. His paintings, however, of the vices of that age are too minute, and too severely faithful to suit the taste of the present day. Amid much inelegance and pedantry, he displays occasional taste, and a fair acquaintance with history, divinity, and Latin literature.

His largest poem, *The Monarchie, ane Dialog betwix Experience and ane Courteour*, seems to have been the work of his advanced age, and is little else than a compendium of universal history, forming the basis, however, of many acute generalizations. A translation of it into Latin prose, by Andrew Robertson, was, in 1591, re-translated into Danish verse by Jacob Mattsön. His *Dreme*, supposed to be his earliest poem, is characterized by Warton as evincing strong talents for high description and rich imagery. In his *Complaynt* there is a lively and faithful sketch of the author's own fortunes, of the manners of the age, and of the gradual corruption of James V., by the designs and vicious example of his courtiers. More amusing and satirical is his *Supplication directit to the Kingis Grace, in contemplation of Side Taillis*; in which, after an unscrupulous exposure of the absurdities of the over-long skirts of the ladies, he concludes that they are the offspring of pride, the parent of all evil. *Kittis Confession*, a satire upon auricular confession, is characterized alike by good sense and severe pungency. A more poisoned weapon, his *Testament and Complaynt of our Sovereign Lordis Papingo* (or Parrot), was aimed at both courtiers and clergy. His *Tragedie of the Cardinall Beaton* is deficient in elegance and vigour. The mock-heroic tilt of two rival leeches of the king's household is cleverly described in his *Justing betwix Watson and Barbour*. In spite of its offences against good taste and decency, the *Historie of Squyer Meldrum* is, perhaps, the most amusing of all his works. The Squire, a contemporary of the author, combines the character of a hero of classical antiquity with that of the hero of more modern romance; but his adventures, though facetiously enough described, bear too strong a similarity to the real events on which they are founded, to be romantic. The most elaborate, however, of all his productions, is the *Satyre of the Thrie Estaitis*, the earliest specimen now extant of the genuine Scottish drama. A moral play, rather than a regular drama, it contains real characters, who mingle freely with impersonations of virtues and vices. Its merciless blows are dealt indiscriminately against the monarch, the nobility, and especially the clergy; a severity, however, which did not prevent it from being represented before the king and his court at Cupar, about 1535, and at Linlithgow about 1539. Its mixture of piety with gross obscenity is almost unexampled.

Besides his poetical works, he left two treatises on Heraldry, the one still in manuscript, and the other a curious collection of blazonings, lately published. The MSS. of these are preserved in the Advocates' Library. Bale, in his *Scriptores Britannia*, attributes to him the *Acta sui Temporis*; and Mackenzie affirms that he was the author of a History of Scotland. There is no sufficient ground for believing, with Dr Leyden, that Lindsay wrote the *Complaynt of Scotland*.

The latest edition of Sir David Lindsay's poems was published, with a life, prefatory dissertation, and glossary, by George Chalmers, London, 1806, 3 vols. 8vo. The chief authorities for the Life of Lindsay are, Lord Lindsay's *Lives of the Lindsays*, and Irving's *Lives of Scottish Poets*.

LINDSEY, REV. THEOPHILUS, an able Socinian writer,

Lindus
||
Linen.

was born in Middlewich, Cheshire, on the 20th June 1723. He was educated at St John's College, Cambridge, where he took degrees, and afterwards obtained a fellowship. After travelling for two years on the Continent with the son of the Duke of Somerset, he was presented in 1753 to the living of Kirkby Wiske, in Yorkshire; and after exchanging it for that of Piddletown, in Dorsetshire, he removed to Catterick, in Yorkshire, where he remained for several years. He began to entertain Anti-Trinitarian views, which were confirmed in 1769 by his intimacy with Dr Priestley and the Rev. William Turner. In 1772 he took great interest in the debate in parliament on a bill to relieve scrupulous persons from subscribing the Thirty-nine Articles; but as the movement failed, he found it necessary to leave the Established Church, although at great personal sacrifice. From 1774 till 1778 he preached in a room in Essex Street, Strand, and afterwards removed to a chapel built for him in the same street. Here he continued to labour till 1793, when old age compelled him to leave the charge of his flock in the hands of Dr Disney, a sufferer in the same cause with himself, who had left the Establishment and become his colleague. Lindsey died 3d November 1808, in the eighty-sixth year of his age. His chief work is, *An Historical View of the State of the Unitarian Doctrine and Worship from the Reformation to our own times*, 8vo, Lond. 1783. His life was written by Thomas Belsham, 8vo, Lond. 1812.

LINDUS (modern *Lindo*), an ancient Dorian town on the E. coast of Rhodes, near a promontory of the same name. It is mentioned by Homer, along with the two other Dorian cities, Ialysus and Camirus, as allied to the Greeks in the Trojan War. After the building of Rhodes (408 B.C.), Lindus soon lost both its population and independent position. It continued famous, however, for the *Lindia*, or temple of Minerva, and the temple of Hercules. The former, of which the ruins may still be seen, was built by the daughters of Danaus, or, according to others, by Danaus himself. The inscriptions found on the tombs, and other architectural vestiges, are described in Hamilton's *Researches*, vol. ii., p. 55. Lindus was the birthplace of Cleobulus, one of the Seven Sages. The district around it, though sterile, was noted in ancient times for wine and figs. See RHODES.

LINEN, a woven fabric prepared from the spun thread of flax (*Linum usitatissimum*), the cultivation of which is noticed under AGRICULTURE, and HEMP; the method of bleaching it is noticed under BLEACHING; and of imparting colour to it, under DYEING. In the present article we propose to notice briefly the modes of preparing linen thread, referring to our general article on WEAVING for an account of the textile fabric.

As soon as the flax has been pulled, it is usual to separate the linseed from the stalk by the process of *rippling*; the ripple consisting of a row of iron teeth about 18 inches long, firmly fixed in a bench or plank: on drawing the stalks briskly through the ripple, the seed bolls are quickly separated. The next process is *retting*, or steeping in water, in order to separate the woody portion of the stalk, or *boon*, from the filamentous portion, which is the flax. The common method of doing this is in pools or pits filled with water, as noticed in one of the previous articles referred to; but it is now done more quickly and economically by means of steam, which effects in about 60 hours that which, under the old process, requires from 10 days to 3 or 6 weeks. Under the new process the flax is steeped in large circular vats, furnished with steam-pipes. The flax is held down in the vats by strong cross-bars of wood; water is then let in

from time to time, until the flax ceases to absorb it. Steam is then made to circulate through the steam-pipe at the bottom of the vat, so as to raise the water to about 90 degrees, and maintain it at that temperature. In the course of a few hours the acetous fermentation has set in, and the resinous or gummy matter, which binds the parts of the stalk together, becomes decomposed, and the decomposition is completed in about 60 hours. The water is then drawn off, and the flax is removed to be dried either in the open air, or in a drying chamber, artificially heated. Improved methods of retting flax, by means of alkaline solutions, with the assistance of pressing rollers and vacuum vessels, have been patented.

The woody portion of the straw, being thus loosened from the filaments, is separated by the processes of *breaking* and *scutching*.

The *break* is a machine consisting of two rows of iron grooves, one fixed to a frame, and the other falling down upon it, in such a way that the convex part of the upper row of grooves falls into the concave part of the under row, and bruises the wood without injuring the fibre. The upper row of grooves is brought down by the action of a treadle, and is raised by means of a spring. The operator passes the flax between these grooves, so as to bruise the boon, and enable it to separate easily under the blade of the scutching-knife, which is a broad wooden blade held in the right hand, while with the left a handful of bruised flax straw is introduced into a groove in a wooden stand, and so beaten with the scutch-blade as to strike away the bits of woody matter. These operations are often performed by machinery, in which rollers are employed to crack the boon, and rotating knives attached to the face of a vertical wheel to separate the woody particles. Mr MacAdams' machinery is on this plan.¹ Mr Plummer, of Newcastle-on-Tyne, has patented a number of machines for the preparation of flax. In his flax-breaking machine the flutes on contiguous rollers are not quite in contact, so that the flax straw in passing between them is not damaged. It is the opinion of this patentee, that in the usual method of scutching and preparing flax for the spinning-mill, the principle has been to attain fineness by reducing and destroying the character of the fibre, rather than supporting the fibre, while undergoing the operation of cleaning. Instead, therefore, of the rigid tools to which flax is usually submitted, brushes of whalebone, bristles, or other suitable materials of various degrees of fineness, are used in most of the preparatory processes. In the rotary disk scutching-mill, an attempt is made to imitate the process of hand-scutching, by passing the flax between a series of disks covered with brushes instead of knives or blades. The flax, while being scutched, is held in a mechanical holder instead of in the hand.

The flax thus freed from its woody particles, is made up into bundles of 16 or 24 lb., the former being termed the *English*, and the latter the *Scotch stone*. The great markets for supplying the spinning trade of the three kingdoms are Leeds, Belfast, and Dundee. The length of the staple in flax may vary from 26 to 30 or 36 inches, and the fibre is of different degrees of fineness in its different parts, that near the root being coarse and strong, the middle portion fine and strong, and the upper part fine, but not so strong. Hence the first operation on the flax in the flax-mill is to divide the lengths into three parts, which are kept separate, and furnish different qualities of thread. The division is made not by cutting, but by tearing the filaments asunder, so as to leave loose ends, which, in spinning, would combine with other similar ends placed upon them. The machine for dividing the flax consists of holding or friction-wheels which move slowly, and hold the flax, while a centre wheel,

Linen.

¹ Mr MacAdam is Secretary to the Society for the Promotion and Improvement of the Growth of Flax in Ireland. He is the author of an essay "On the Cultivation of Flax," which gained the prize offered by the Royal Agricultural Society of England. The essay is inserted in the 8th vol. of the Society's *Journal*.

Linen. furnished with oval projections on its periphery, tears the fibres asunder. With flax of long staple, four or five divisions may be made instead of three.

The heaps or *stricks* of flax thus formed are cleaned, split, separated into fibres in parallel order, while the short fibre or tow is separated by the process of *heckling*. The *heckle* or *hackle* is a sort of comb with iron or steel teeth, very sharp at the points, arranged on a block of wood. Heckles are of various degrees of fineness; and, in some cases, the teeth being set close together, a heckle may contain more than a 1000, arranged in parallel rows. By throwing the flax upon these teeth, and drawing it out, the tow is combed out, and the long fibre or *line*, as it is called, remains; 100 lb. of well-cleaned flax yielding from 45 lb. to 60 lb. of line; the rest being tow, boony particles, and dust. In some cases, between the first and second hecklings, the flax is folded up in a bundle and beaten on a block with a wooden mallet, after which it is well rubbed in the hands. Heckling is also commonly performed by machinery, for which purpose the lengths of flax of 10 or 12 inches are spread out and fixed in an iron vice or holder; a number of these holders are hung on to a circular frame, within which revolves a drum covered with sharp heckling teeth, the outer frame revolving more slowly in the contrary direction, and depositing the holders upon a rail after they have passed through about half a circle. The holders are then turned the other way, so that the other portion of the fibres may be heckled. After this the holders are opened, the flax is inverted, and again passed through the machine. Mr Plummer has several improved heckling machines, both for cut flax and for long flax; he objecting to the plan of cutting up the flax into lengths, and maintaining that if a long and generous fibre be treated with gentleness instead of harshness, considerable saving may be effected. In the double heckling machines both sides of the flax are brushed before it meets with the heckling points or pins, by which means crossed or entangled fibres are got rid of.

The next operation in the mill is *sorting* the heckled flax or line, so as to separate the stricks into various degrees of fineness, which is done as much by the touch as by the eye, while the fibres are frequently drawn through a block-heckle to keep them parallel. The sorted line is placed in certain boxes or divisions marked respectively—2 lb., 3 lb., 3½ lb., 4 lb., 5 lb., 5½ lb., 6½ lb., and so on; from an old method of comparing fineness and weight.

The sorted line is now subjected to the operations of *spreading*, *drawing*, and *roving*, whereby it is converted into ribbons or *slivers*. It is spread upon a feeding-cloth, in such a way that the ends of the second strick reach the middle of the first; by which means a uniform thickness is maintained, the heckle-stricks being thicker in the middle than at the ends. The feeding-cloth delivers the flax to a pair of rollers, and these pass it on through gills or heckling-points to a second pair, which, moving at greater speed, increase the length and diminish the thickness of the line, so as to convert it into a flat narrow sliver or ribbon, which is received by a tin can. This being full, it is taken to a drawing or spreading frame, where a number of slivers are united and drawn into one length. This drawing is as important for flax as for cotton, and is sometimes repeated three or four times, increasing the number of drawings each time. After this the drawings pass through a roving-frame, where they are slightly twisted, and are then wound upon bobbins preparatory to spinning. The spinning-wheel has, during many years, been superseded for flax as well as for cotton; and the machinery employed for the one resembles that used for the other; only as the fibres of flax do not so readily unite as those of cotton, it is necessary for fine work to moisten them, so as to make them more pliable and easy to spin. The water usually employed is raised to the temperature of about 120°.

and is contained in a trough, which extends the whole length of the throstle or spinning-frame.

The fineness of the yarn thus formed is estimated by the number of leas to the pound weight, the lea consisting of 300 yards. Less than twenty years ago, the fineness of machine-spun linen yarn was stated at 150 leas to the pound. Of late years, from 200 to 240 leas line has been spun. It is used in the manufacture of Irish lawns and coarse cambrics; but for fine work, such as the lawns and handkerchiefs of Cambrai and Valenciennes, hand-spun yarns are preferred; some of which, as shown in the Great Exhibition, particularly those exhibited by Messrs Berthelot and Bonté, of Cambrai, are, to use the words of the Jury Report "surprisingly fine, perfect, and beautiful; being up to 1200's warp, and 1600's weft yarn; and are certainly equal, if not superior, to anything of the kind hitherto produced."

It has been already noticed that the various qualities of line are sorted into 2 lb., 3 lb., 3½ lb., and so on. A bundle of linen yarn, consisting of 20 hanks, of 10 leas each, or 60,000 yards, is sometimes named by the number of leas to the pound, or by its weight, thus: a bundle of 25 leas per pound weighs 8 lb.; a bundle of 50 leas per pound weighs 4 lb.; one of 100 leas per pound weighs 2 lb.; so that 8 lb., 4 lb., and 2 lb. correspond in size with 25 leas, 50 leas, and 100 leas. Now, in sorting, a certain quantity of line will spin to a certain size or weight per bundle; and it was long usual with the line sorters, to name certain qualities as 2 lb., 3 lb., 3½ lb., &c.; because that quality of line would spin to that weight per bundle. Line sorters still retain the same standard and name, although, from various improvements in the trade, much finer line can be spun from the same weight than formerly.

Linen thread is made by doubling the yarn, and after bleaching, it is formed into balls or reels.

The foreign trade in the linen manufacture is considerable. Our exports of linen yarn for the years 1853, 1854, 1855, were,—22,893,566 lb., 17,696,567 lb., and 17,872,950 lb., respectively; of which the declared values were,—L.1,154,977, L.944,502, and L.916,429. The value of linen thread exported during the same years was,—L.388,374, L.315,685, and L.293,819; while the exports of linen, entered by the yard, exclusive of lace of thread, during the same years, were respectively,—134,165,291 yds., 111,648,657 yds., 118,247,498 yds.; of the declared values of L.4,345,600, L.3,763,107, and L.3,803,487. During the same years the exports of lace of thread were,—578,623 yds., 292,563 yds., and 218,508 yds.; of the respective values of L.8267, L.7296, and L.4451. Among the imports the most considerable are cambrics and French lawns, which previously to the 11th June 1853 were entered by the piece, but since that date by the square yard. During the years 1854, 1855, there were imported 146,454 square yards, and 154,966 square yards. In 1855 there were imported,—of damasks and damask-diaper, 8219 square yards; of plain linen and diaper, and manufactures not enumerated, and not made up, to the value of L.21,262; while among articles made up, the chief article is cambric handkerchiefs, of which 45,471 were imported. Of the raw material imported in the year 1855, we have—of dressed flax, 14,568 cwts.; undressed, 1,131,475 cwts.; and of tow, or codilla of flax, 147,392 cwts.

During the Great Exhibition of 1851, the attention of the Jury, Class XIV., was attracted by manufactures in China grass; and it was remarked that, in the coarse kinds of cloth made from it, the fibre appeared to be split into lengths which were attached to each other at the smaller ends. There were also some beautiful handkerchiefs and other fine linens made from this material. It is sometimes used for making coloured fabrics, combined with other substances, such as silk and cotton; and the peculiar brilliancy of its fibre allows it to be used in this way to advantage. (C: T)

Linen.

Lingard
||
Lingen.

LINGARD, REV. JOHN, D.D. and LL.D., the Roman Catholic historian of England, was born at Winchester, 5th February 1771. His parents, who were in humble circumstances, belonged to the Church of Rome, and it was chiefly due to the notice taken of him by Dr Milner, that he was sent to study at Douay, in France. He continued to reside here till the revolutionary troubles dispersed the students; and after several changes he came with the staff of the college to settle at Ushaw, near Durham. His first publication was made in 1805, and consisted of a series of letters, written for the Newcastle *Courant*, and collected under the title of *Catholic Loyalty Vindicated*. He was soon afterwards engaged in an attack on Bishop Huntingford, Bishop Tomlin, and Lord Kenyon, in regard to opinions which they had published on the Catholic question, as it was called; and as his strictures called forth antagonists of inferior name, Lingard's replies multiplied into a volume, which was given to the world in 1813, with the title, *A Review of certain Anti-Catholic Publications*. Previously, however, to the collection of these detached pamphlets, he had published (in 1812), *Documents to ascertain the sentiments of British Catholics in former Ages, in regard to the Power of the Popes; Strictures on Doctor Marsh's Comparative View of the Churches of England and Rome in 1815; and Catechetical Instructions on the Doctrines and Worship of the Catholic Church*. His *History and Antiquities of the Anglo-Saxon Church*, a work on which great part of Dr Lingard's fame will rest, was published in one volume in 1806; but in subsequent editions it has been enlarged to two volumes. His English translation of the New Testament was published anonymously in 1836.

But Dr Lingard's greatest work is the *History of England, from the first Invasion by the Romans to the Accession of William and Mary in 1688*. It was first published in 6 volumes 4to, in 1819-25, and has since passed through many editions, and been translated into several languages. The research displayed in this work, the remarkable impartiality on all controverted subjects, except that of his religion, the ease and spirited grace of the composition, the picturesqueness and graphic power of many of his descriptions, and the fresh materials dug out of regions previously unexplored, render this history an instructive and fascinating work. That it is a party history of very high merit, exhausts all that can with justice be said of it either in praise or blame. The author, of course, condemns Anne Boleyn, and defends Queen Katherine; and he instinctively prefers Bonner to Cranmer, and the short reign of Mary to the long annals of Elizabeth's power. In respect of civil and religious liberty, he is, with all his learning and research and genius, little better than a monk of the middle ages. All this, however, constitutes the peculiar value of his work, as furnishing one of a set of forces destined, each in its own place, to affect the resultant of public opinion. In the *Edinburgh Review* (vols. 42 and 44), two papers written by Dr John Allen, preferred a charge of untruthfulness against Dr Lingard, especially in regard to his quotations, which the reviewer held to be garbled for party purposes. This called forth a *Vindication* from Dr Lingard in 1826, and since that time there has been a much more favourable estimate of his merits even in the pages of that journal (vol. 53).

When his *History of England* was published, Dr Lingard visited Rome, and Pope Leo XII. proposed to make him a cardinal, but Dr Lingard declined the honour. He had a pension of £300 a-year from Her Majesty during the closing years of his life, in acknowledgment of his literary talent. He died at Hornby, near Lancaster, on the 13th of July 1851, and bequeathed his library to St Cuthbert's College, at Ushaw, near Durham.

LINGEN, or LINGA, an island of the Malay Archipelago, on the equator, off the N.E. coast of Sumatra, E. Long. 104. 40. It is about 40 miles in length by 20 miles in

breadth. There is a curious mountain in the centre of the island, termed "The Ass's Ears," from the two peaks at the S.W. end. The coast is flat, stretching inland for some miles. Some gold and tin are to be found. The principal products are sago, pepper, farinaceous roots, fruits, and vegetables. The inhabitants are said to be Malays of the purest type, and they are governed by a sultan, whose court is at Rovwala Dai. Pop. 10,000.

LINKÖPING, an ancient town and bishop's see of Sweden, capital of a cognominal län, on the Stänga, 2 miles S. of its junction with Lake Roxen, and 108 miles S.W. of Stockholm. Its streets are rather irregular, but the houses are well built. The chief public buildings are,—the Gothic cathedral, the third in importance in Sweden; and the college, to which are attached a library containing upwards of 30,000 volumes, and a museum of natural history, archæology, and coins. The chief manufactures are stockings and tobacco. Near the bridge which here spans the river the famous battle of Stångebro was fought on the 25th September 1596, between Sigismund and his uncle, afterwards Charles IX. of Sweden, when the latter was victorious. Pop. about 4000.

LINKÖPINGS LÄN, of which the above town is capital, lies between Lake Wetter on the W., and the Baltic on the E., and contains an area of 4254 square miles, with (in 1850) 222,484 inhabitants. The Gota and Motala canals traverse it from the Wetter to the Baltic, and communicate with the many lakes of the district. Its chief products are,—grain, flax, hops, timber, iron, and lead. Linköping and Norrköpping are the two chief towns.

LINLITHGOW, a town of Scotland, capital of the county of that name, and once a place of some commercial importance, its merchants formerly dealing extensively in Baltic produce, is pleasantly situated in the vicinity of a beautiful lake, 16 miles from Edinburgh, and 31 E. from Glasgow. It consists chiefly of a single street, running E. and W. along the S. bank of the lake, containing many substantial though old houses, and is gradually improving in appearance, in consequence of the increasing number of modern buildings. The place from which Hamilton of Bothwellhaugh shot the Regent Murray is still pointed out. The name is supposed to signify "the valley of the flowing lake," from the circumstance, it is believed, that the supply of water is chiefly derived from springs flowing from its bed. It is a very ancient town, having been erected into a royal burgh by David I. The oldest charter extant, however, is in 1389 by King Robert II. It possesses the ruins of a fine old palace, the birth-place of Queen Mary, and a favourite residence of the Scottish monarchs, built at different periods, on the site of a castle erected by Edward I. of England (who with his army wintered at Linlithgow in 1301), and which was destroyed by fire in 1746. It has also a very ancient church, in the decorated Gothic style, said to have been founded by David I., but little of the original structure now remains. In its south transept appeared the vision of St John, a probable device of his nobles to dissuade James IV. from his intended war with England, as described by Pittcottie. There are four Protestant places of worship unconnected with the Established church, besides a Roman Catholic place of worship. The old fountains are objects of much curiosity. The town has a dull appearance, but the inhabitants are by no means inactive, having a considerable trade in tanning, gluemaking, and shoemaking; besides which, paper-manufacturing, calico-printing, and distillation are carried on on a large scale. It is also surrounded by extensive fields of coal and iron, and is in consequence increasing in importance. The Edinburgh and Glasgow Railway and Union Canal intersect the burgh. There is a weekly grain stock market held on Friday. The population in 1851 amounted to 4213, and the parliamentary constituency in 1856 to 124. Linlithgow

Linköping

Linlithgo

Linlithgowshire.

along with the burghs of Airdrie, Falkirk, Hamilton, and Lanark, returns one member to parliament.

LINLITHGOWSHIRE, or WEST LOTHIAN, a county in Scotland, having the Firth of Forth on the N., Edinburghshire, or Mid-Lothian, on the E. and S.E., Lanarkshire on the S.W., and Stirlingshire on the W., is situate between N. Lat. 55. 49. and 56. 1., and W. Long. 3. 18. and 3. 51. It is of a triangular form, about 19 miles long on its eastern boundary, and 13 on its western; but at a medium it is only about 7 miles broad, and 16 long. It contains 79,995 imperial acres, or about 125 square miles.

The surface of this county generally is either level or serrated into gently undulating ridges, running from E. to W., and separated from each other by a succession of irregular miniature valleys. Towards the W. and S.W. the ground rises into a succession of hills, the most elevated peak of which, Cairnpapple, in the parish of Torphichen, is about 1000 feet above the level of the sea. The county is in general beautifully wooded, and the trees have reached a large size.

The climate, though variable, is not severe, and the neighbourhood of Linlithgow is considered to be remarkably salubrious. The prevailing winds, which blow for about two-thirds of the year, are from the S.W. According to a register of the weather kept at Duddingston, on the coast of the Firth of Forth, about the middle of the northern boundary, the greatest number of rainy and snowy days in one year, for a period of thirty years, from 1778 to 1808, was 111 (in 1780), and the smallest number 22 (in 1803), but the days on which slight showers fell are not included. The quantity of rain, however, that falls in this county exceeds somewhat that in Mid-Lothian, and amounts to a fourth part more than the fall in East-Lothian, which, in an agricultural point of view, is not considered as disadvantageous.

Though there is a great variety of soil in this district, and considerable tracts of gravel and sand, yet clay is the most general. Upwards of four-fifths of the soil is arable, and capable of producing every description of crop cultivated in Scotland. The best land is situate to the N. and E., along the shores of the Firth of Forth; and the worst is found on the high table-lands in the parishes of Whitburn and Torphichen, being in an opposite direction. The high grounds, from the prevalence of mountain limestone, afford excellent pastures, and are generally adorned with thriving plantations. A considerable quantity of moor still exists in the upland parishes, but much has of late been reclaimed.

The only streams of note are,—the Almond, which rises on the border of Lanarkshire, and flows N.E. for about 24 miles between this county and Edinburghshire; and the Avon, which forms the western boundary for about 12 miles. Both these fall into the Firth of Forth. On the N. side of the town of Linlithgow there is a lake about a mile long, and half-a-mile broad, occupying about 150 acres, and abounding with pike and eels. In the parishes of Linlithgow, Ecclesmachan, and Abercorn, there are several sulphurous springs, and a strong chalybeate is found in the parish of Torphichen; but none of them are resorted to.

Argentiferous galena was at one time got in the Cairnpapple ridge, in the parish of Linlithgow; and in the neighbourhood of that town a small vein of that ore was found several years ago in a limestone quarry. Limestone is wrought in the high grounds to the S.W. of the town of Linlithgow, and at Hopetoun, near Queensferry. Sandstone, in some places of an excellent quality, prevails along the coast of the Forth, and in the interior there are whinstone and basalt. At Binny, in the parish of Linlithgow, is found the celebrated freestone which has been used in the erection of the Royal Institution, National Gallery, and a considerable part of the chief public buildings in Edinburgh and Glasgow. On Dundas Hill there is a basaltic rock 250

VOL. XIII.

Linlithgowshire.

yards in length, and about 60 feet in height, with an almost perpendicular front, consisting of a fine texture. Coal has been wrought in the county of Linlithgow for five centuries past, and it is supposed that supplies of that article were obtained at Bonnytown Hill, near Linlithgow, in the time of the Romans. In the vicinity of Borrowstounness coal has long been wrought to a great extent; and within the last fifteen years the discovery of large fields of common and blackband ironstone, together with the increased facilities of transit, has contributed greatly to the development of the mineral wealth of the county in that quarter. In the neighbourhood of Bathgate is found the celebrated Torbanehill and Boghead gas coal or Bitumenite; and extensive mineral fields have, more recently, been discovered there also. The following is a statement, from the valuation-roll of the county for 1856-7, of the rents and lordships realized for minerals:—

1. In Bathgate parish	L.4480	10	0
2. „ Borrowstounness	6542	7	4
3. „ Carriden	6121	3	10
4. „ Ecclesmachan	170	18	0
5. „ Torphichen	489	17	6
6. „ Whitburn	3667	13	4
7. „ Uphall	160	9	9

Total.....L.21,632 19 9

Smelting furnaces on an extensive scale have been erected at Kinniel, in the lower, and at Crofthead, in the upper, part of the county; and at Bathgate paraffine oil is extracted in great quantities from the Bitumenite. The principal collieries now in operation are,—Colinshiel, Grange, Kinniel, Barbauchlaw, Polkemmet, Coustoun, and Benhar.

The valued rent of the county, taken in 1649, was L.75,027, 12s. 2d. Scots. In 1806 the real rent was L.64,518, 18s. 7d. sterling; in 1811 the real rent of land, mines, and houses, was L.88,745, 10s.; in 1844 the real rent was L.114,822, 17s. 6d.; and, in 1856, including railways and canals, it amounted to L.156,792, 12s. 8d. The rental of the county has thus become more than doubled in the course of fifty years.

The principal mansion-houses are,—Hopetoun House, Earl of Hopetoun; Dalmeny Park, Earl of Rosebery; Kinniel House, Duke of Hamilton; Dundas Castle, Mr Dundas of Dundas; Craigie Hall, Mr Hope Vere; Polkemmet House, Sir William Baillie, Bart.; Wallhouse, Mr Gillon; Preston, Mr Seton; Avontoun, Mr Blair; and Newliston, Mr Hog.

The arable land is divided into farms of from 100 to 400 imperial acres, and the rent per acre of these varies from 30s. to 60s. The average rent of the county in 1811 was rather more than 23s. per imperial acre; and in 1856, after deducting the value of mines, canals and railways, and inhabited houses, it was found to be more than 27s. 6d. per acre. The leases of the arable land are almost invariably for nineteen years; and grass lands are usually let annually by public roup, although in some instances they are taken for a period of three or five years. The system of farming is not inferior to that pursued in the best cultivated districts, and is principally in the four or six year course rotation; but many of the minor farmers have large dairies, and find a ready market for their produce amongst the rapidly increasing mining population of the county.

The following are the agricultural statistics of Linlithgowshire for 1856:—Number of occupants, 458; total acreage under a rotation of crops, 52,511;—wheat, 4643; barley, 3789; oats, 12,520; rye, 2; bere, 51; beans, 1776; pease, 2; vetches or tares, 509; turnips, 5142; potatoes, 2044; mangold, 45; carrots, 13; cabbage, 12; flax, 105; turnip seed, 59; any other grain or root crop, 53; bare or summer fallow, 340; grass and hay under rotation, 21,400. Horses for agricultural purposes above 3 years old, 1659; ditto under 3 years old, 467; other horses, 452; milk cows, 3446; other cattle, 6103; calves, 1797; sheep for

Linnæus. breeding, 4471; ditto for feeding, 7229; lambs, 4813; swine, 1494.

There are two royal burghs in the county—Linlithgow and Queensferry; and, besides the towns of Bathgate and Borrowstounness, which are increasing rapidly in population, there are a number of thriving villages. The county is divided into thirteen parishes, and contains also a portion of the parish of Cramond, which is chiefly in the county of Edinburgh. These parishes, with two in Mid-Lothian, and four in Stirlingshire, form the Presbytery of Linlithgow. It sends one member to parliament, and the constituency, in 1856, amounted to 427. It is united with the counties of Berwick, Haddington, and Peebles, in furnishing a regiment of militia artillery.

The county is intersected by several lines of railways,—the Edinburgh and Glasgow Railway, one of the trunk lines, passing through it from E. to W. for a distance of about 10 miles. The Edinburgh and Bathgate connects the port of Leith and the extensive mineral fields in the south of the county and Lanarkshire; and the Wilsontown and Morning-side, and several others, complete the connection with the mineral fields of the west. By the Monkland, Slamannan, and Borrowstounness railways, a large amount of coal and iron is brought for shipment at that town (which is rapidly rising in importance as a shipping port), and a considerable portion of the produce of the Kinniel iron-works are transported to Glasgow. The Edinburgh and Glasgow Union Canal traverses from 10 to 11 miles of the county, upon which there is a large traffic in manure, coal, and freestone.

The site of the Roman wall, which extended from the Forth to the Clyde, usually styled "Grahame's Dyke," is still pointed out in the parishes of Borrowstounness and Carriden. In the latter parish there is a farm establishment which still bears the name of "Walltown;" and in the former the Duke of Hamilton's fine estate is denominated "Kinniel," or "the head of the wall." The remains of a stone barrow exists near Kippe, about 3 miles to the S. of Linlithgow. A preceptory, which originally belonged to the Knights-Templars, and afterwards to the Order of St John of Jerusalem, is to be seen at Torphichen, and a portion of it is used as the parish church. The parish churches of Dalmeny, Abercorn, Kirkliston, Uphall, and the burgh church of South Queensferry, are also of great antiquity. Pop. (1831) 23,291, (1841) 26,872, (1851) 30,044.

LINNÆUS, or LINNÉ, SIR CHARLES, a celebrated botanist and natural historian, was born on the 24th of May 1707, in a village called Roshult, in Smaland, where his father, Nicholas Linné or Linnæus, was then vicar, but afterwards preferred to the curacy of Stenbrohult. It is said, that on the farm where Linnæus was born there yet stands a large lime tree, from which his ancestors took the surnames of *Tiliander*, *Lindelius*, and *Linnæus*.

It seems probable that Linnæus' taste for the study of nature was formed from the example of his father, who, as he has himself informed us, cultivated, as his first amusement, a garden plentifully stored with plants. Young Linnæus soon became acquainted with these, as well as with the indigenous plants of his neighbourhood. Yet, from the smallness of his father's income, the young naturalist was on the point of being destined to a mechanical employment; fortunately, however, this design was overruled. In 1717 he was sent to school at Wexio, where, as his opportunities were enlarged, his progress in all his favourite pursuits was proportionally extended. At this early period he paid attention to other branches of natural history, particularly to the study of entomology.

The first part of his academical education Linnæus received at Lund, in Sweden, under Professor Stobæus, who favoured his inclination for the study of natural history. After a residence of about a year, he removed in 1728 to

Uppsala. Here he soon contracted a close friendship with *Linnæus.* Artedi, a native of the province of Angermania, who had already been four years a student in that university, and, like himself, had a strong bent to the study of natural history in general, but particularly to that of ichthyology. Soon after his residence at Uppsala, our author was likewise fortunate enough to obtain the favour of several gentlemen of established character in literature. He was in a particular manner encouraged in the pursuit of his studies by the patronage of Dr Olaus Celsius, at that time professor of divinity, and the restorer of natural history in Sweden; who, being struck with the diligence of Linnæus in describing the plants of the garden at Uppsala, and his extensive knowledge of their names, not only patronized him in a general way, but admitted him to his house, his table, and his library. After a residence of only two years at Uppsala, he was thought sufficiently qualified to give lectures occasionally from the botanic chair, in the room of Professor Rudbeck.

In the year 1731, the Royal Academy of Sciences at Uppsala, having for some time meditated the design of improving the natural history of Sweden, at the instance particularly of Professors Celsius and Rudbeck, deputed Linnæus to make the tour of Lapland, with the view of exploring the natural history of that arctic region; an undertaking to which his reputation, already high as a naturalist, and the strength of his constitution, equally recommended him. He left Uppsala on the 13th of May, and took his route to Gevalia or Gevels, the principal town of Gesticria, forty-five miles distant from Uppsala. Thence he travelled through Helsingland into Medelpad, where he made an excursion, and ascended a remarkable mountain on his way to Hudwicksvald, the chief town of Helsingland. He then proceeded through Angermanland to Hernosand, a seaport on the Bothnian Gulf, seventy miles distant from Hudwicksvald; and, as the spring was not sufficiently advanced, he took this opportunity of visiting, though at the hazard of his life, the remarkable caverns on the summit of Mount Skula.

When Linnæus arrived at Umcea, in West Bothnia, about ninety-six miles from Hernosand, he quitted the public road, and took his course through the woods westward, in order first to traverse the southern parts of Lapland. Having now reached the country that was more particularly the object of his inquiries, being equally a stranger to the language and to the manners of the people, and without any associate, he committed himself to the unfailing hospitality of the inhabitants. In this excursion he reached the mountains towards Norway; and after encountering great hardships, returned into West Bothnia. He next visited Pithœa and Lulea, upon the Gulf of Bothnia; from which latter place he again took a westerly route, proceeding up the river of that name, and visited the ruins of the temple of Jockmock in Lulea Lapland, or Lap Mark; he thence traversed what is called the *Lapland Desert*, destitute of all villages, cultivation, roads, or any conveniences, and inhabited only by a few straggling people, originally descended from the Finlanders, a people entirely distinct from the Laplanders. In this district he ascended a noted mountain called Wallovär, in speaking of which he has given us a pleasant relation of his finding a singular and beautiful new plant (*Andromeda tetragona*) when travelling within the arctic circle, with the sun in his view at midnight, in search of a Lapland hut. Thence he crossed the Lapland Alps into Finmark, and traversed the shores of the North Sea as far as Sallero.

These journeys from Lulea and Pithœa, on the Bothnian Gulf, to the north shore, he performed on foot, attended by two Laplanders, one his interpreter, and the other his guide. He tells us that the vigour and strength of these two men, both old, and sufficiently loaded with his baggage, excited his admiration, since they appeared quite unfatigued by their labour; whilst he himself, although young and robust,

Linnæus. was frequently quite exhausted. In this journey he was wont to sleep under the boat with which they forded the rivers, as a defence against rain, and the gnats, which in the Lapland summer are not less teasing than in the torrid zone. In descending one of these rivers, he narrowly escaped perishing by the upsetting of the boat, and lost many of the natural productions which he had collected.

Linnæus thus spent the greater part of the summer in examining this arctic region, and those mountains on which, four years afterwards, the French philosophers secured immortal fame to Sir Isaac Newton. At length, after having suffered incredible fatigues and hardships, in climbing precipices, passing rivers in miserable boats, suffering repeated vicissitudes of heat and cold, and not unfrequently hunger and thirst, he returned to Tornea in September. He did not take the same route from Tornea as when he set out for Lapland, having determined to visit and examine the country on the eastern side of the Bothnian Gulf. His first stage, therefore, was to Ulea, in East Bothnia, and thence to Old and New Carlebay, 84 miles south from Ulea. He continued his route through Wasa, Christianstadt, and Biorneburg, to Abo, the only university in Finland. Winter was now setting in apace; he therefore crossed the gulf by the island of Åland, and arrived at Upsala in November, after having performed, mostly on foot, a journey of ten degrees of latitude in extent, exclusive of those deviations which such a design rendered necessary.

In 1733 he visited and examined the several mines in Sweden, and made himself so well acquainted with mineralogy and the docimastic art, that he was sufficiently qualified to give lectures on these subjects upon his return to the university. The outlines of his system of mineralogy appeared in the early editions of the *Systema Naturæ*; but he did not exemplify the whole until the year 1768.

In the year 1734 Linnæus was sent by Baron Reuterholm, governor of Dalecarlia, with several other naturalists in that province, to investigate the physical productions of that part of the Swedish dominions; and it was in this journey that he first laid the plan of an excellent institution, which was afterwards executed, in a certain degree at least, by himself, with the assistance of many of his pupils, and the result published under the title of *Pan Suecicus*, in the second volume of the *Amanitates Academicæ*.

After the completion of this expedition, it appears that Linnæus resided for a time at Fahlun, the principal town in Dalecarlia, where he tells us that he taught mineralogy and the docimastic art, and practised physic; and where he was very hospitably treated by Dr More, the physician of the place. It also appears that he contracted at this time an intimacy with one of that gentleman's daughters, whom he married about five years afterwards, upon his settling as a physician at Stockholm. In this journey he extended his travels quite across the Dalecarlian Alps into Norway; but we have no particular account of his discoveries in that kingdom. In 1735 Linnæus travelled over many other parts of Sweden, some parts of Denmark and Germany, and fixed his residence in Holland, until his return to Stockholm about 1739. In 1735, the year in which he took the degree of doctor of physic, he published the first sketch of his *Systema Naturæ* in the form of tables, in 12 pages folio.

In 1736 Linnæus arrived in England, and visited Dr Dillenius, the learned professor at Oxford, whom he justly considered one of the first botanists in Europe. It is needless to say, that he visited Dr Martyn, Mr Rand, and Mr Miller, and that he was in a more singular manner indebted to the friendship of Dr Isaac Lawson. He also contracted an intimate friendship with Mr Peter Collinson, which was reciprocally increased by a multitude of good offices, and continued to the last without any diminution. Dr Boer-

haave had furnished him with letters to Sir Hans Sloane; but these, it seems, did not procure him the reception which the warmth of his recommendation appeared to claim.

One of the most agreeable circumstances that happened to Linnæus during his residence in Holland, arose from the patronage of Mr Clifford, in whose house he lived a considerable part of his time, being now as it were the child of fortune. *Exivi patriâ triginta sex nummis aureis dives*, are his own words. With Mr Clifford, however, he enjoyed pleasures and advantages scarcely at that time to be met with elsewhere in the world; that of a garden excellently stored with the finest exotics, and a library furnished with almost every botanic author of note. How happy he found himself in this situation, those only who have felt the same kind of ardour can conceive. Whilst in Holland, Linnæus was recommended by Boerhaave to fill the place, then vacant, of physician to the Dutch settlement at Surinam; but he declined it on account of his having been educated in so opposite a climate.

Amongst his friends at this period may be mentioned Dr John Burmann, professor of botany at Amsterdam, whose name and family are well known in the republic of letters, and to whom our author dedicated his *Bibliotheca Botanica*, having been greatly assisted in compiling that work by the free access he enjoyed to that gentleman's excellent library; John Frederick Gronovius, of Leyden, editor of Clayton's *Flora Virginica*, and who very early adopted Linnæus's system; Baron Van Swieten, physician to the empress queen; Isaac Lawson, afterwards one of the physicians to the British army, who died much regretted, at Oosterhout, in the year 1747, and from whom Linnæus received singular and most obliging civilities; Kramer, well known for an excellent treatise on the docimastic art; Van Royen, botanic professor at Leyden; and Liëberkun of Berlin, famous for his skill in microscopical instruments and experiments. To these may also be added the names of Albinus and Gaubius, and of others, were it requisite to show that our author's talents had very early rendered him conspicuous, and gained him the regard of all those who cultivated medical science; and to which, doubtless, the singular notice with which Boerhaave had honoured him did not a little contribute.

Early in 1738, after Linnæus had left Mr Clifford, and probably when he resided with Van Royen, he had a long and dangerous attack of sickness; and upon his recovery went to Paris, where he was kindly entertained by the Jussieus, at that time the first botanists in France. The opportunity this gave him of inspecting the *Herbaria* of Royen and Tournefort, and those of the above-named gentlemen, afforded him great satisfaction. He had intended to proceed from thence into Germany, to visit Ludwig and Haller, with whom he was in close correspondence; but he was not able to complete this part of his intended route, and was obliged to return without this gratification.

Our author did not fail to avail himself of the advantages which access to the several museums of this country afforded him, in every branch of natural history; and the number and importance of his publications, during his absence from his native country, sufficiently demonstrate that fund of knowledge which he must have imbibed before, and no less testify his extraordinary application. These were,—*Systema Naturæ*, *Fundamenta Botanica*, *Bibliotheca Botanica*, and *Genera Plantarum*; the last of which is justly considered as the most valuable of all the works of this celebrated author. The immense application bestowed upon it the reader may easily conceive, when he is informed, that before the publication of the first edition, the author had examined the characters of 8000 flowers. His last work, published during his stay in Holland, was the *Classes Plantarum*, which is a copious illustration of the second part of the *Fundamenta*.

Linnæus.

About the latter end of 1738, or the beginning of 1739, Linnæus settled as a physician at Stockholm, where he seems to have met with considerable opposition, and was oppressed by many difficulties; but all of these he at length overcame, and got into extensive practice; and, soon after his settlement, married the lady before mentioned. By the interest of Count Tessin, he obtained the rank of physician to the fleet, and a stipend from the citizens for lecturing on botany. And what at this time especially was highly favourable to the advancement of his character and fame, by giving him an opportunity of displaying his abilities, was the establishment of the Royal Academy of Sciences at Stockholm, of which Linnæus was constituted the first president, and to which the king granted several privileges, particularly that of free postage to all papers directed to the secretary. By the rules of the academy, the president held his place but three months. At the expiration of that term, Linnæus made his *Oratio de memorabilibus in Insectis*, on the 3d of October 1739; in which he endeavours to excite an attention and inquiry into the knowledge of insects, by displaying the many singular phenomena that occur in contemplating the nature of those animals, and by pointing out, in a variety of instances, their usefulness to mankind in particular, and to the economy of nature in general.

During all this time, however, Linnæus appears to have had his eye fixed upon the botanical and medical chair at Upsala, then occupied by Rudbeck, who was far advanced in life. Indeed, so intent was he on pursuing his favourite study, that he had determined, if he failed in procuring the professorship at Upsala, to accept the offer which had been made to him by Haller, of filling the botanic chair at Göttingen. However, in course of time, he obtained his wish. In 1741, upon the resignation of Roberg, he was constituted joint professor of physic, and physician to the king, with Rosen, who had been appointed in the preceding year on the death of Rudbeck. These two colleagues agreed to divide the medical departments between them; and their choice was confirmed by the university. Rosen took anatomy, physiology, pathology, and the therapeutic part; Linnæus, natural history, botany, materia medica, dietetics, and the diagnosis morborum.

During the interval of his removal from Stockholm to Upsala, in consequence of this appointment, our professor was deputed by the states of the kingdom to make a tour to the islands of Oeland and Gothland, in the Baltic, attended by six of the pupils, commissioned to make such inquiries as might tend to improve agriculture and arts in the kingdom, to which the Swedish nation had for some time paid particular attention. The result of this journey was very successful, and having proved fully satisfactory to the states, was afterwards communicated to the public. On his return he entered upon the professorship, and on the 17th of October pronounced before the university his *Oratio de Peregrinationum intra Patriam necessitate*, in which he forcibly displays the usefulness of such excursions, by pointing out to the students that vast field of objects which their country held out to their cultivation, whether in geography, physics, mineralogy, botany, zoology, or economics, and by showing the benefit that must accrue to themselves and their country as rewards of their diligence. The animated spirit which pervades the whole of this composition renders it one of the most pleasing and instructive of all our author's productions.

Linnæus was now fixed in the situation which was the best adapted to his character, his taste, and abilities; and which seems to have been the object of his ambition, and the centre of his hopes. Soon after his establishment, he laboured to get the academical garden, which had been founded in 1657, put upon a better footing, and very soon effected it, procuring also a house to be built for the resi-

dence of the professor. The whole had been in ruins ever since the fire in 1702; and at the time Linnæus was appointed professor of botany, the garden did not contain above fifty plants that were exotic. His correspondence with the first botanists in Europe soon supplied him with great variety. He received Indian plants from Jussieu of Paris, and from Van Royen of Leyden; European plants from Haller and Ludwig; American plants from Mr Collinson, Mr Catesby, and others; and a variety of annuals from Dillenius: in short, how much the garden owed to his diligence and care in a few years, may be seen by the catalogue published under the title of *Hortus Upsaliensis, exhibens Plantas Exoticas horto Upsaliensis Academiae a sese (Linnæo) illatas, ab anno 1742 in annum 1748, additis differentiis Synonymis, Habitationibus, Hospitiis, rariorumque Descriptionibus, in gratiam Studiosæ Juventutis*, Holm. 1748, 8vo. By this catalogue it appears that the professor had introduced 1100 species, exclusively of all the Swedish plants and varieties, which, in ordinary gardens, amount not unfrequently to one-third of the whole number. The preface contains a curious history of the climate at Upsala, and the progress of the seasons throughout the whole year.

From the time that Linnæus and Rosen were appointed professors at Upsala, the credit of that university, as a school of physic, increased. Numbers of students resorted thither from Germany; and in Sweden itself many young men were invited to the study of physic, who otherwise would have engaged in different pursuits.

Whilst Linnæus was meditating one of his capital performances, long expected and greatly wished for, he was interrupted by a tedious and painful attack of the gout, which left him in a very weak and dispirited state; and, at this juncture, nothing seemed to contribute more to the restoration of his spirits than the seasonable acquisition of a collection of rare and undescribed plants.

The fame which our author had now acquired by his *Systema Naturæ*, of which a sixth edition, much enlarged, had been published at Stockholm in 1748, in 8vo, with eight tables explanatory of the classes and orders, had brought, as it were, a conflux of everything rare and valuable in every branch of nature, from all parts of the globe, into Sweden. The King and Queen of Sweden had their separate collections of rarities, the former at Ulricksdahl, and the latter, very rich in exotic insects and shells, procured at a great expense, at the palace of Drottningholm, both of which our author was employed in arranging and describing. Besides these, the museum of the Royal Academy of Upsala had been augmented by a considerable donation from the king, whilst hereditary prince, in 1746, by another from Count Gyllenborg the year before, and by a third from M. Grill, an opulent citizen of Stockholm.

From this time the professor appeared in a more elevated rank and situation in life. His reputation had already procured him honours from almost all the royal societies in Europe; and now his own sovereign favoured him with a mark of distinction and regard, by creating him a Knight of the Polar Star. With science, it was no longer *laudatur et alget*. His emoluments kept pace with his fame and honours; his practice in his profession became lucrative; and we find him soon after possessed of a country-house and gardens at Hammarby, about 5 miles from Upsala. He had, moreover, received one of the most flattering testimonials of the extent and magnitude of his fame that perhaps was ever shown to any literary character, the state of the nation, which conferred it, and all its circumstances, being duly considered. This was an invitation to Madrid from the King of Spain, there to preside as a naturalist, with the offer of an annual pension for life of two thousand pistoles, letters of nobility, and the unrestricted exercise of his own religion. But after the most grateful acknowledgments of

Linnæus.

Linnæus. this singular honour, he respectfully answered, "that if he had any merits, they were due to his own country."

In 1755 the Royal Academy of Sciences at Stockholm honoured our professor with one of the first premiums, agreeably to the will of Count Sparree, who had decreed two gold medals, of ten ducats value each, to be annually given by the Academy to the authors of such papers, in the preceding year's *Stockholm Acts*, as should be adjudged most useful in promoting agriculture in particular, and all branches of rural economy. This medal bore on one side the arms of the Count, with this motto, *Superstes in scientiis amor Frederici Sparree*. Linnæus obtained it in consequence of a paper *De Plantis quæ Alpium Suevicarum indigenæ, magno rei œconomicae et Medicæ emolumento fieri possint*; and the ultimate intention was to recommend these plants as adapted to culture in Lapland. This paper was inserted in the *Stockholm Acta* for 1754, vol. xv. Linnæus also obtained the *præmium centum aureorum*, proposed by the Imperial Academy of Sciences at St Petersburg, for the best paper written to establish or disprove, by new arguments, the doctrine of the sexes of plants. It was an additional glory to Linnæus to have merited this premium from the St Petersburg Academy, inasmuch as a professor of that society, a few years before, had, with more than common zeal, although with a futility like that of the other antagonists of our author, endeavoured to overturn the whole Linnæan system of botany, by attempting to show that the doctrine of the sexes of plants had no foundation in nature, and was unsupported by facts and experiments.

It appears that Linnæus, upon the whole, enjoyed a good constitution; but that he was sometimes severely afflicted with a *hemiplegia*, and was not exempted from the gout. About the close of 1776 he was seized with an apoplexy, which left him paralytic; and at the beginning of the year 1777 he suffered another attack, which very much impaired his mental powers. But the disease supposed to have been the more immediate cause of his death, was an ulceration of the urinary bladder, of which, after a tedious indisposition, he died, on the 11th January 1778, in the seventy-first year of his age. His principal works, besides those already mentioned, are—The *Iter Oëlandicum et Gotlandicum*; *Iter Scanicum*; *Flora Suecica*; *Fauna Suecica*; *Materia Medica*; *Philosophia Botanica*; *Genera Morborum*; different papers in the *Acta Upsaliensia*, and the *Amœnitates Academicæ*. The last of his treatises was the *Mantissa Altera*, published in 1771; but before his death he had finished the greater part of the *Mantissa Tertia*, afterwards completed and published by his son.

To the lovers of science it will not appear strange that uncommon respect was shown to the memory of this great man. We are told, "that on his death a general mourning took place at Upsala, and that his funeral procession was attended by the whole university, as well professors as students, and the pall supported by sixteen doctors of physic, all of whom had been his pupils." The King of Sweden, after the death of Linnæus, ordered a medal to be struck, one side of which exhibits Linnæus's bust and name, and the other Cybele, in a dejected attitude, holding in her left hand a key, and surrounded with animals and growing plants, with the legend, *Deam luctus angit amissi*; and beneath, *Post Obitum Upsaliæ, die x. Jan. M.DCC.LXXVIII. Rege jubente*. The same generous monarch not only honoured the Royal Academy of Sciences with his presence when Linnæus's commemoration was held at Stockholm, but, as a still higher tribute, in his speech from the throne to the assembly of the states, he lamented Sweden's loss by his death.

Linnæus's stature was diminutive; his head was large, and its hinder part very high; his look was ardent, piercing, and apt to daunt the beholder; his ear was insensible

to music; and his temper quick, but easily appeased. Nature had been eminently liberal in the endowment of his mind. He possessed a lively imagination, corrected by a strong judgment, a most retentive memory, unremitting industry, and the greatest perseverance in all his pursuits. This is evident from the continued vigour with which he prosecuted the design formed so early in life, of totally reforming and constructing anew the whole science of natural history. This fabric he raised to a degree of perfection unknown before; and had the uncommon felicity of living to see his own structure rise above all others, notwithstanding every discouragement. Neither has any writer more cautiously avoided the common error of building his own fame upon the ruin of another man's. He ever acknowledged the merits of each author's system; and no man appears to have been more sensible of the partial defects of his own. Those anomalies which had principally been the objects of criticism he well knew that every artificial arrangement must abound with; and having laid it down as a maxim, that every system must finally rest on its intrinsic merit, he willingly committed his own to the judgment of posterity. Perhaps there is no circumstance of Linnæus's life which shows him in a more dignified light than his conduct towards his opponents.

The great improvement in descriptive natural history for which we are indebted to Linnæus, is the systematic introduction of *trivial* or specific names to designate species. Before his time, the *genus* of a plant or an animal was given, but the species was defined generally by a short description of its peculiarities—a clumsy and difficult method when the species were numerous; but Linnæus added another name to the generic one, to designate each species—as *Quercus Robur*, for the common oak; *Pinus Picea*, for pitch pine; *Canis Lupus*, for the wolf; *Fringilla Domestica*, for the common sparrow; *Rana Temporaria*, for the common frog; *Salmo Salar*, for the salmon.

LINNHE, LOCH, an arm of the sea, on the W. coast of Scotland, stretching into N. Argyllshire, and separating the district of Lorn from those of Morven and Sunart. It is 22 miles long from the southern extremity of Lismore Island to the mouth of Loch Eil, by 4 in average, and 12 in extreme breadth, at its entrance. It sends off four branch lochs,—viz., Lochs Etive, Creran, Leven, and Eil; and contains several islands, the chief of which are,—Lismore, Shuna, and Balnagowan. It communicates with the Caledonian Canal through Loch Eil. The scenery of its coasts is highly picturesque.

LINT. See HEMP, LINEN, and WEAVING.

LIN-TSING, a large and populous town of China, province of Shangtung, on the Imperial Canal, at its junction with the Eu-ho River, about 200 miles S. of Peking. A famous pagoda, nine storeys high, stands here, built of porphyry, granite, and varnished bricks, besides several temples, one of which contains a colossal idol of gold. A large trade is carried on here by means of the canal.

LINUS, the impersonation of a dirge (*λύρος*), is represented as the son of Apollo, and one of the muses. According to one myth, Linus, having been exposed in his infancy by his mother, came under the foster care of shepherds, but was afterwards torn to pieces by dogs. Another fable says that he was slain by Apollo for his audacity in vieing with that god in a musical contest. His statue stood in a grotto near Mount Helicon. At Thebes and Argos, his death was annually solemnized by the singing of dirges, called *λύροι*; and these two cities, along with Chalcis, contested the honour of possessing his tomb. Another Linus, of later date, is supposed to have been the music instructor of Hercules, and to have been killed by that hero. He is the reputed author of several poems.

LINZ, or LINTZ, a city of the Austrian empire, capital of Upper Austria, situate chiefly on the right bank of the Danube;

Linnhe
li
Linz.

Lipari
Islands.

at its junction with the Traun, here crossed by a wooden bridge, 900 feet long, 105 miles W. of Vienna; N. Lat. 48. 19., E. Long. 14. 17. The city is situate in a beautiful part of the country. It has three suburbs, which are larger than the city proper. It is entered by four gates, and is surrounded by a cordon of forts, of which twenty-three are on the right bank of the Danube, and nine on the left. They communicate with each other by a covered way, which is fully 9 miles in circuit. The streets are, on the whole, spacious and well built, and this has been the effect of not a few destructive fires. There are, however, few public buildings of importance. In the Landhaus, which was formerly a Franciscan convent, the parliament of Upper Austria holds its meetings. On an eminence overlooking the Danube, and rising above the rest of the town, is a castle, formerly inhabited by the dukes of Austria, but now used as a prison and penitentiary. In the largest square stands a column to the Holy Trinity, erected by Charles VI. in 1723; and beside it are two fountains, adorned with statues. The only other buildings worthy of note are,—the bank, the theatre, the custom-house, and a large government establishment for the manufacture of carpets. Linz is the see of a bishop, and possesses a cathedral and seven churches. The Matthias Kirche contains a monument of the celebrated Montecuculi. There are also a lyceum, with a theological and philosophical faculty, a large library, and a number of good schools. The charitable institutions are numerous.

The imperial factory, together with the other establishments of this kind, are engaged principally in the manufacture of woollen, cotton, and silk goods, leather, cards, and tobacco; and trade in these articles has greatly extended since the opening of the railway (a tramroad on the American plan) to Gmünden and Budweis, and since, Linz has been a station for steamers on the Danube.

Linz is supposed to have been originally a Roman station, and retained its name of Lentia during the middle ages. In 1036 it was purchased by Leopold II., margrave of Austria. It was attacked in 1626 by Fahdinger, the peasant leader, but it held out successfully. Pop. 31,000.

LIPARI ISLANDS, a group of islands lying off the N. coast of the island of Sicily, to which they belong, forming part of the intendency of Messina, between N. Lat. 38. 20. and 38. 55., and E. Long. 14. 15. and 15. 15. They consist of seven principal islands,—Lipari, Vulcano, Stromboli, Salini, Panaria, Felicudi, and Alicudi, and a number of adjacent islets and rocks. They are all mountainous, rising abruptly on their W. side to a considerable height, and sloping down gradually towards the E. They are evidently volcanic in their origin; and ancient writers mention several active volcanoes, though only one is at present in a state of action,—that on the island of Stromboli, which is constantly burning. The fires in the crater of Vulcano still emit sulphurous vapours; and the soil was burning hot when Spallanzani visited it in 1788. In 1786 it erupted a vast accumulation of sand, with much smoke and flame. The basis of the whole group is hornstone, which is covered with lava, scoræ, pumice-stone, and other volcanic products. The soil thus formed is very absorbent in its character, and hence the inhabitants are obliged to construct capacious cisterns, in which rain-water is carefully preserved for irrigation and other purposes. The land is fertile and well cultivated, producing grapes, currants, figs, prickly pears, corn, cotton, olives, beans, pease, &c. Violent rains sometimes cause great injury to the grounds, owing to their situation and the friability of the soil; and at other times swarms of locusts do great injury to the crops. The cattle are lean and not abundant, as the pasturage is for the most part only adapted to the feeding of goats. Wine and raisins are largely exported, as well as bitumen, pumice, nitre, pozzolano, cinnabar, coral, and fish. Alum at one time formed a considerable article of export, but it has decreased

in quantity, probably in consequence of the diminished heat of the subterranean fires. Some sulphur is still exported, though much less than formerly, owing to a prejudice entertained by the inhabitants that the vapour which arises from its purification infects the air, and is injurious to vegetation. The climate is highly salubrious, and the air mild and refreshing. Storms and earthquakes, however, are frequent. Pop. about 23,000.

Lipari, the largest and most important island of the group, has an area of about 110 square miles, with a population of about 15,000. It is, for the most part, hilly or mountainous, with, however, valleys and plains of great beauty and fertility, producing a much esteemed malmsey wine. Wheat, cotton, beans, pease, and various kinds of fruits, are among its other vegetable products. On several of the mountains are craters of extinct volcanoes. There are also thermal springs in different parts of the island. Lipari, the chief town of the island, and the capital of the whole group, is situate on a steep declivity on the E. side of the island, in N. Lat. 38. 27. 56., E. Long. 14. 57. 50. It is a bishop's see, and the residence of a military governor, and has a commodious harbour with good anchorage. The town is irregularly built, with narrow and dirty streets. The principal public building is the cathedral. The castle, the greater part of which was built by Charles V. after Barbarossa had plundered the town, stands on a large volcanic mass, and incloses the cathedral and some other edifices. A large trade is carried on in the products of this and the other islands. Pop. 12,500.

The Lipari Islands were by the ancients termed *Æolia Insula*, from their king, Æolus, who is fabled to have received from Jupiter power over the winds. They were also called *Hephestiades*, or *Vulcania insula*, as sacred to the god Vulcan, and *Liparenses*, from *Lipara*, the principal of the group. Lipara is said to have been so called from Liparus, son of Auson, one of its kings who flourished before the time of Æolus. It was colonized about B.C. 580, by Dorians from Cnidus and Rhodes, who, as they increased in numbers, extended themselves to the adjoining islands of Didyme, Hieria, and Strongylo. The necessity of defending themselves against the Tyrrhenian pirates led to the establishing of a naval force, with which they themselves not unfrequently resorted to piracy. At the commencement of the first Punic War, in B.C. 264, this island was subject to the Carthaginians, and became an important naval station. Captured by C. Aurelius in B.C. 251, it continued ever after a part of the Roman empire.

LIPETSK, a town of Russia, government of Tambov, 80 miles W. of the town of that name, on the right bank of the Voroniej. In the neighbourhood are well-frequented mineral springs. Pop. about 8000.

LIPPA, a market-town of Hungary, county of Temesvar, on the left bank of the Maros, 30 miles N.E. from Temesvar. The inhabitants are chiefly engaged in agriculture, cattle-rearing, and the potteries, excellent clay being abundant in the vicinity. Some trade in grain, cattle, wine, honey, &c., is carried on. Pop. about 8000.

LIPPE-DETMOLD, a German principality, bounded E. and N.E. by Hanover, Hesse-Cassel, and Lippe-Schaumburg, and on the other sides by Prussian Westphalia, is situate between N. Lat. 51. 45., and 52. 10., E. Long. 8. 34. and 9. 20.; area 438 square miles. It is mountainous and well wooded, interspersed with fertile valleys; an extensive chain of forests called the Teutoburger Wald passes through it, and in the S.W. lies the Senner Heath. The country derives its name from the River Lippe, which rises in the Teutoburger Wald, and joins the Rhine at Wesel. The Weser, which is its most important river, has for its tributaries the Emmer, Exter, Kalle, Bega, and Werra. The Ems passes through the Senner Heath and enters Westphalia. The climate in winter is cold, but in summer

Lipetsk
||
Lippe-
Detmold.

Lippe-
Schaumburg
||
Lippi,
Fra Filippo.

it is mild, although somewhat misty and wet. In a country so thickly wooded, the value of the timber, which consists principally of oak and beech, is very great. Of the other natural productions, flax is the most important, but corn, rapeseed, and hemp are also produced in large quantities. The horses bred in the Senner Heath are much prized; horned cattle and sheep are reared in large numbers, and there is a considerable trade in honey. Limestone, gypsum, and iron are the principal mineral products. There are also several saline springs, one of which is said to yield 36,000 bushels of salt annually. There is, on the whole, little manufacturing industry; but in some places there are paper and saw mills, glass-works, and weaving establishments. The principal exports are timber, flax, thread, linen, and wool. The government is a constitutional monarchy; the diet, which consists of the prince and a representative body, meets once in two years; and whilst the states vote in two separate assemblies on questions in general, they vote in one assembly on the question of taxation. Lippe-Detmold furnishes about 700 men to the federal army. The most of the inhabitants belong to the Reformed Church. Pop. (1855) 105,490.

Bernard VIII., who died in 1563, was the first of the ancient house of Lippe who took the title of Count of Lippe. His son, Simon VI., became sole lord of all the lands of Lippe, and it is from him that the present reigning family has descended.

LIPPE-SCHAUMBURG, a principality of N.W. Germany, comprised between Hanover, Lippe-Detmold, and Prussian Westphalia, and having an area of 207 square miles. The country is hilly, especially towards its southern extremity, but the northern portion is level. The Schaumburger Wald is a very large forest in the W. In the N. is the Steinhuder Meer, a small and shallow lake. There are no rivers in the country, except a few very small streams which flow into the Weser. Coals and lime are the mineral products, of the former of which the Bückeberg contains some rich seams. The soil is remarkably productive, yielding turnips, potatoes, flax, rapeseed, corn, and pulse; and of live stock, sheep, horned cattle, pigs, and poultry are reared in great numbers. The manufactures consist principally of linens; and there is a considerable trade in the exportation of the natural products of the country. The government is a constitutional monarchy, and, as a member of the German confederation, it has one vote in the full diet; and, with Lippe-Detmold, &c., occupies the sixteenth place in the confederation. It furnishes 200 men to the federal army. Pop. (in 1855) 29,848.

LIPPI, FRA FILIPPO, was born in Florence in 1412. His father and mother died while he was yet a child, and his father's sister, Mona Lappaccia, sent him, when eight years of age, into the Carmelite convent Del Carmine. The prior, perceiving his inclination and talent for drawing, wisely permitted him every day to study the paintings in the convent chapel, and to be present when Masaccio was engaged in painting them. Lippi profited so well by his visits to Masaccio, that his frescoes on the walls of the convent and church soon became equal to those of his master. Their works in this place, however, were destroyed by fire in 1771.

Elated with his success in painting, Lippi threw off the clerical habit in 1430, and retired to Ancona. Here, when on a pleasure excursion, he and his companions were seized by a Moorish vessel and carried off to Barbary, where he remained for eighteen months in a state of slavery. He owed his liberation to his favourite art. One day, for amusement, he sketched on a wall, with a piece of charcoal, a portrait of his master, who, surprised and delighted with this proof of the young painter's skill, released him from prison, and after he painted some other pieces for him, sent him to Naples in safety. For Alfonso, the Duke of Cala-

bria, he executed a work on panel, which was placed in the chapel of the castle; but he soon left Naples for Florence, where he painted an admirable picture for the nuns of Sant' Ambrogio, which was the means of bringing him under the notice of Cosmo de' Medici. About the same time he painted a work for the chapter-house of Santa Croce, another for the chapel of the Medici palace, and a third for the wife of Cosmo de' Medici, all of which still exist in the picture galleries of Florence. Lippi was restless and fond of sensual pleasure; and, on one occasion, when employed by Cosmo, it was thought necessary to imprison him beside his work; but the impetuous artist, after two days' confinement, made ropes from the sheets of his bed, and dropped himself from the window into the street.

In 1459 he was commissioned by the nuns of Santa Margherita, to paint an altar-piece, when he was so much struck by the beauty of Lucrezia, the daughter of Francesco Buti, who lived in the convent, that he begged the nuns to let him paint her likeness for the Virgin in his picture. They consented, and greatly to their grief, Lippi carried off the young lady. They had a son called Filippo Lippi, who also became a distinguished painter.

Fra Filippo Lippi died at Spoleto in 1469, being at that time 57 years of age. Some have maintained that he was poisoned by the relations of Lucrezia, but this does not seem probable. His death was deeply regretted by very many, and by none more than by his friend Pope Paul II. Lorenzo de' Medici, anxious to do the great painter honour, asked his remains from the Commune of Spoleto, in order that they might be placed in the Cathedral Santa Maria del Fiore, at Florence. The people of Spoleto begged to have the honour of retaining them, and Lorenzo then, at his own expense, placed a marble monument to his memory in the cathedral at Spoleto.

One of the greatest works of this master is his *Death of San Bernardo*, painted for the caputular church of Prato (and still there); and *The Life of Stephen*, in three parts, namely, "The Disputation," "The Stoning," and the "Death of the Protomartyr." This is, perhaps, the finest specimen of the artist's genius. On the other side of the chapel is his *History of John the Baptist*, in which he has painted his own portrait and that of Lucrezia. There are also *The Annunciation*, *St Jerome doing Penance*, and many others. His paintings are characterized by inventive genius, admirable drawing, good colouring, and great power in expressing deep emotion.

LIPPI, Filippo or Filippino, the son of Fra Filippo Lippi, was born in 1459. After the death of his father, he was brought up and instructed by Sandro Botticelli, and also to some extent educated by Fra Diamante. He soon exhibited great invention, and devoting himself ardently to the study of Roman antiquities, introduced into his works banners, mantles, the toga, buskins, helmets, and arms of every description. He was one of the first painters who devoted much attention to such embellishments. At Florence, he completed the chapel of the Brancacci, introducing the portraits of several of his friends. In his picture of *Peter Condemned to Death*, we have his own portrait as a young man; but as he never painted it again, we cannot obtain any likeness of him at a more advanced time of life. He went to Rome on the invitation of Lorenzo de' Medici to paint a chapel for Cardinal Caraffa. He chose for his subject *Events from the Life of Thomas Aquinas*; but he introduced a good deal of fictitious matter into these compositions. He returned to Florence, and painted the Strozzi Chapel, in the church of Santa Maria Novello; on one side is the *Resurrection of Drusiana by John the Evangelist*, and on the other, *San Filippo in the Temple of Mars*. His works are very numerous, but the best are those above mentioned. He died in 1505, in the forty-fifth year of his age.

Filippo.

Lippi,
Lorenzo
||
Lipsius,
Justus.

LIPPI, *Lorenzo*, an historical and portrait painter, and a poet, was born at Florence in 1606, and was educated in painting by Matteo Roselli. Some of his works closely resemble those of his master. His *Crucifixion* and *Triumph of David*, are his best pictures; the former of these is in the Florentine gallery. He painted a good many excellent portraits at Innsprück, which are still to be seen there. His paintings are admired for their simplicity, elegance, and correct drawing. His genius in poetry was evinced by a burlesque, entitled *Malmantile Racquistaro*, published under the fictitious name of Perloni Zipoli. It appeared first at Florence in 1688, 4to, and subsequent editions were published at Florence in 1731, and at Paris in 1768. Lippi died in 1664, in the fifty-eighth year of his age.

LIPPSTADT, a walled town of Prussian Westphalia, government of Arnsberg, and 23 miles N.N.E. of the town of that name, on the left bank of the Lippe. It is entered by five gates, and has a court-house and an orphan hospital. It has brandy distilleries, and manufactures of woollens, leather, vinegar, and starch. A part of it formerly belonged to Lippe-Detmold. Pop. 4862.

LIPSIUS, *Justus*, an eminent critic and antiquary, was born on the 18th of October 1547, at Isque, a village between Brussels and Louvain. After receiving his elementary education at Brussels, he began, at the age of ten, to study Latin at Ath, in Hainaut; and after the lapse of two years, entered the Jesuit College at Cologne. There applying himself to history, philosophy, and Greek, he gave so fair a promise of future eminence, that the Jesuits, who were eager to employ the talents of their pupils in their own service, used all their arts to draw him within their fraternity. Their designs, however, were defeated by his parents, who removed him, in 1564, to the University of Louvain. In addition to his favourite studies of philology and philosophy, Lipsius, at the desire of his father, who had destined him for the legal profession, now began to study jurisprudence. The death of his father, however, in the ensuing year, left him to follow the full bias of his own mind. His first work, *Variarum Lectionum libri tres*, published in 1567, and dedicated to Cardinal de Granvelle, secured for him the patronage of that ecclesiastic, who appointed him his Latin secretary. In this capacity he accompanied the cardinal in that same year to Rome, where he remained till 1569, cultivating an intimacy with several learned men, and poring over the manuscripts preserved in the Vatican and other libraries. On his return to Louvain, he spent a year there with little profit either to his learning or morals. He then set out on a tour, and after travelling in Austria, was passing through Germany towards Louvain; but receiving an alarming account of the war that was raging in the Netherlands, he was induced to settle down at Jena as professor of history and eloquence. After retaining this office for two years, he removed to Cologne in 1574, and there he married a lady descended from a good family in Louvain. In the same year his first edition of *Tacitus* was printed in octavo at Antwerp. He improved the succeeding editions with great assiduity; and the sixth edition, in folio and quarto, was printed at the same place in 1600. His *Antiquarum Lectionum libri quinque* appeared at Antwerp in 1575.

From Cologne, after a sojourn of nine months, he retired to Isque; but upon the renewal of hostilities in the vicinity, he withdrew to Louvain. Here, at the suggestion of his friends, he resumed the study of jurisprudence, and in 1576 took the degree of LL.D. His knowledge of law, though never used professionally, aided his critical labours by elucidating many points in Roman antiquities. In 1577 he published his *Epistolicarum Quaestionum libri quinque*. He became professor of history at Leyden in 1579, and taught there with high reputation. At Louvain he had been a Papist, at Jena a Lutheran, and at Leyden he now became a Calvinist.

At Leyden he produced some of his more elaborate works. *Liquation*. His *Electorum liber primus* appeared in 1580; *Electorum libri duo* in 1582; *De Amphitheatro liber*, to which is subjoined *De Amphitheatris quæ extra Romam libellus* in 1584; *Saturnalum Sermonum libri duo* in 1585; *De recta Pronuntiatione Latine Lingue Dialogus*, dedicated to Sir Philip Sidney, in 1586; and an edition of Seneca's *Tragedies* in 1588. He also published two political works,—*De Constantia libri duo*, in 1584; and *Politiorum sive Civilis Doctrinæ libri sex*, in 1589. This latter treatise, advocating the punishment of dissenters from the established faith, was immediately attacked by Theodore Koornhert, and feebly defended by its author in his *De Una Religione adversus Dialogistam liber*, published 1590. Resigning his chair in 1591, he withdrew to Spa, and afterwards to Mentz; and in the same year was publicly reconciled to the Romish Church. During a sojourn of two years at Spa and Liège, he refused several preferments proffered to him by princes and dignitaries of the Church. Benedictus Arias Montanus, a learned Spaniard, also offered him a share of his house and income during his life, and promised him his entire property after his death. His desire to reside in his native country induced him, however, to reject this offer; and Lipsius finally returned to Louvain as professor of history and eloquence. Here his scanty salary of 800 florins was supplemented by a pension of 1000 florins from Philip II., and one of 200 from Archduke Albert. The high eminence he attained as a professor was confirmed by the publication of the following antiquarian works:—*De Cruce libri tres*, 1595; *De Militia Romana libri quinque*, and *Poliorecticon*, 1596; *Admiranda, sive de Magnitudine Romana libri quatuor*, 1598; and *De Vesta et Vestalibus* in 1603. His *Manuductionis ad Stoicam Philosophiam libri tres*, and his *Physiologiae Stoicorum libri tres*, appeared in 1604; his *Monita et Exempla Politica*, his edition of Seneca the philosopher, and his *Lovanium*, in 1605. He also wrote two detailed accounts of the miracles of the Virgin,—*Diva Virgo Hallensis*, in 1604, and *Diva Sichemiensis*, in 1605. These, furnishing the subject of a bitter controversy, aroused the contempt of Protestants, without securing any sympathy for their promulgator in the Church of Rome. Lipsius died March 23, 1606, dedicating, with his last breath, his academical gown to the Virgin.

His erudition in Latin literature was very great, and was employed with much critical skill in illustrating many different branches of Roman antiquities. Less adapted, through a defective sensibility, to excel in poetical criticism, he was still an able critic of the style and scope of historians, philosophers, grammarians, and rhetoricians. His knowledge of Greek was less intimate; and his exposition of Polybius, incorporated with his *De Militia Romana*, is asserted by Casaubon to have shed no light on the dark passages of the original. The graver charge of plagiarism has been brought against this same work by Scaliger, Salmassius, and many later writers. Nor has his edition of Tacitus, the chief pillar of his fame, escaped this stigma. That his judgment was weak, when beyond the province of criticism, is evinced by the shortsighted views and illiberal spirit of his political treatises. His Latinity, fantastic and unnatural, excited the disgust of his learned contemporaries, and was the subject of a volume of 560 pages by H. Stephanus. In the hands of a few imitative disciples it underwent a tenfold deterioration.

An edition of his entire works, accompanied by a life, was published at Antwerp in 1637, by Aubert le Mire. His original works were published at Wesel in 1675.

LIQUATION, or ELIQUATION, a method of reducing the ores of silver by forming a triple alloy of copper, silver, and lead, which being cast into round masses, are placed on edge in a furnace on an inclined plane of iron, contain-

Liquorice
||
Lisbon.

ing a small channel, and raised to a red heat; as the lead melts out, by its attraction for silver it carries that metal with it, leaving the copper as a reddish-black spongy mass. The silver is recovered by one of the methods described under LEAD. See also ASSAYING. (C. T.)

LIQUORICE, a well-known vegetable product, which was equally known to the ancients, who used it medicinally. This plant, as employed by the ancient physicians, is believed to have been the *glycyrrhizé* of Dioscorides and *glycyrrhizion* of Pliny. The root is obtained from a perennially herbaceous plant, the *Glycyrrhiza glabra*. Met with in some parts of Austria, it inhabits chiefly the deep light soils of Southern Europe, especially Spain, Italy, and France. It is much cultivated in England for medicinal purposes, particularly at Pontefract in Yorkshire, and Micham in Surrey. The root is long, creeping, and succulent, and about the thickness of the thumb, from which shoot forth several simple stems, from two to four feet high. The stems are covered with large, unequally pinnate, yellowish-green leaves of a viscous nature, and bear axillary, racemose, papilionaceous flowers of a whitish colour with purple tips, and succeeded by smooth four-seeded pods.

Liquorice-root consists of lignin, starch, wax, resinous oil, colouring matter, albumen, malic acid, earthy phosphates and sulphates, an azotized crystalline principle and glycion, or glycyrrhine. Liquorice is prepared in Spain, Italy, and Sicily, from the root of *G. glabra* only by inspissating the decoction in copper kettles till the mass is sufficiently thick to be firm when cooled. Made up into sticks of 6 inches long and dried on the leaves of the sweet bay, it is thus imported into Britain. The finest liquorice comes from Italy. It is of a brownish-black colour, smooth, shining and flexible when warm, brittle when cold, and of a very sweet taste. Water dissolves from three-fifths to eleven-twelfths of it; alcohol only about an eighth. The imported liquorice does very well for making lozenges, but when used for sweetening decoctions or as an excipient for pills, it requires to be purified. The extract of the root, when brought into this country, is commonly called Spanish liquorice, or liquorice juice. It is sometimes imported run into boxes of about 2 cwt. each, in which form it is said to be purer than when in sticks. The Russian liquorice root met with occasionally on the continent, but unknown in this country, is inferior to the common, and is said to be cultivated in preference to the ordinary liquorice plant from its greater power of enduring cold. The most dangerous adulteration to be met with in liquorice is copper, obtained from the pans in which it is prepared.

LIRIA (the ancient *Edeta*), a town of Spain, province of Valencia, and 17 miles N.W. of the town of that name. Though mean and neglected in appearance, it has some good buildings among its ecclesiastical structures. On the summit of a hill in the vicinity is the Colegio de San Miguel, an extensive and venerable pile with a handsome and richly decorated church. The inhabitants are chiefly agricultural, but some manufactures of linen, soap, leather, earthenware, &c., are carried on. Pop. about 8000.

LISBON (*Lisboa*, in Portuguese), the metropolis of Portugal, and the chief town of one of the seventeen administrations into which the kingdom is divided, is situate on the right bank of the Tagus (*Tejo*), about 9 miles from its mouth, in N. Lat. 38. 42., and W. Long. 9. 5. It is, therefore, distant about 900 miles in a straight line from London. The ground upon which it stands is very uneven, and hence it is often said to be built upon seven hills, like ancient Rome. Its situation is very fine, and its appearance from the deck of a vessel sailing up the river is highly imposing. Indeed, there are very few cities in the world which present so impressive a *coup d'œil* as Lisbon, viewed from the Tagus. The river is deep enough to float vessels of the largest burden; and here are usually seen several

British men-of-war, surrounded by craft of all sizes from all nations. Lisbon.

The origin of Lisbon is lost in remote antiquity; but there are not wanting fables to carry back its foundation some thousands of years before the Christian era; whilst others attribute its origin to the wandering Ulysses, and affect to trace its name in that of the Ithacan king. Pliny states that its first inhabitants were a warlike tribe called Turduli. It passed successively into the hands of the Phœnicians, Greeks, Carthaginians, and Romans. Julius Cæsar bestowed upon it the title of *Felicitas Julia*, and the rights of a *municipium*. The barbarians who overran the peninsula about A.D. 409 wrested Lisbon from the Romans. The Goths under Theodoric subsequently obtained possession of it, but it passed from them to the Arabs with the rest of the peninsula, after the battle (711) wherein Roderick, *ultimus Rex Gothorum*, was slain. Taken from them by the Spaniards, it soon became Moorish again, but was finally conquered from the invaders in 1147 by Alphonso, first King of Portugal, after a siege of several months, in which he was assisted by an army of crusaders, chiefly English, on their way to the Holy Land. The city was very obstinately defended; but the statement that 200,000 Moors perished during the struggle is doubtless an exaggeration of the victors. About 1372, in the reign of Ferdinand the Handsome, Lisbon was burnt by the King of Castile in the course of a quarrel which arose out of the claim of the Portuguese king to the crown of Castile. Soon after Ferdinand's death, Lisbon was besieged by the Spaniards, but not taken. During the 60 years (1580-1640) that Portugal was subject to Spain, Lisbon fell to the rank of a provincial town. It was captured by the Duke of Bragança, afterwards John IV., in 1640. In 1755 occurred that terrible earthquake, which, assisted by a fire which broke out, reduced the city to a heap of ruins, and destroyed between 30,000 and 40,000 people, with an immense amount of property. Shocks of earthquake, of more or less violence, have been experienced at Lisbon through many centuries, but none has caused such damage and loss of life as that of 1755. The minister Pombal, a man of great talent and energy, applied himself, in the first place, to the preservation of the rights of property, and then to the reconstruction of the city. The handsomest part of the present city was erected under his direction; but even now there are many ruined edifices which speak forcibly of the great *terremoto* and its horrors. When Napoleon issued his decree that the House of Bragança had ceased to reign in Europe, the Regent Don John was compelled to desert the country for Brazil, and the next day a French army under Junot entered Lisbon (29th November 1807); possession of which was retained until the 15th September 1808, when Junot quietly embarked his army under the protection of the disgraceful Convention of Cintra.

In the absence of an authoritative census, the population of Lisbon may be roughly estimated at 250,000. With this number of inhabitants it ranks amongst the most populous capitals of Europe, and is much before Madrid, with only 176,000 inhabitants. The separate households amount to about 47,800; and the city with its suburbs is divided into 39 parishes, containing 354 streets, 216 lanes, 12 large squares, 5 public gardens, and 34 fountains. There are three royal palaces, four theatres, and a circus for bull fights. Until of late years, travellers have had just reason to complain of the filthy state of the streets. (Byron, it will be remembered, speaks in *Childe Harold* of the many "things unsightly to strange ee.") But things have been much altered for the better, and, except in some of the small out-of-the-way streets, there is now little to find fault with either as regards the paving, the lighting, or the cleanliness. Gas made from British coal was introduced about the year 1850. Excellent water flows to the fountains distributed

Lisbon. throughout the city, from which it is removed in barrels to the houses by *Gallegos*, men from Galicia who do the principal part of the hard work in Lisbon. The supply of water is not, however, in summer adequate to the requirements of the place, and a company has been lately formed for the obtaining of a further supply.

Lisbon stretches along the shore of the Tagus for 4 or 5 miles, and extends northward over the hills for nearly 3 miles. Much of it, however, is scattered; and in all but the densest parts, there are gardens and unoccupied patches. For municipal purposes the city is divided into four districts (the whole under one municipal chamber), and two suburban districts, under separate chambers. The crown is represented by the civil governor, who is at the head of the police. For the most part the streets are very irregular; but that portion which suffered most from the great earthquake, and which had to be wholly rebuilt, is occupied by lofty houses, arranged in long streets, on a uniform plan. Here are the four principal squares. One of these squares, the *Praça do Commercio*, is surrounded on three sides by the custom-house and government offices, with a spacious arcade beneath. On the fourth it is open to the river; and in the middle is a grand equestrian statue, in bronze, of Joseph I., in whose reign the earthquake and the rebuilding took place. This is the only statue in the city. The square is 583 feet by 536, and its appearance is strikingly handsome. From one side of it run several parallel streets, which terminate in another handsome square, the *Praça de Don Pedro*, surrounded on three sides by large houses, the ground stories of which are used as shops; whilst on the fourth side stands the new theatre of Dona Maria II. A grand triumphal arch is being erected in the former square, at the termination of the principal street connecting the two. The public gardens are small, but much frequented. The hotels of Lisbon, notwithstanding the great influx of strangers, offer only indifferent accommodation; whilst the shops present little display, and are ill-supplied with wares.

The palace where the king actually resides (the *Palacio das Necessidades*) is a large unsightly building, to which a good garden is attached. The palace of *Ajuda*, in the Italian style, situate upon a hill above the suburb of *Belem*, was commenced upon a very grand scale, but has been left incomplete. Receptions, however, sometimes take place here. It contains a good library, and some bad pictures. If ever finished, it will be one of the handsomest palatial edifices in Europe. Several of the nobility have good and spacious houses in the city, which are dignified by the name of palaces. Two or three small forts, one on a rock at the mouth of the Tagus, defend the city from the approach of a hostile fleet; but its chief defence is the citadel of St George, which occupies a commanding position on a rocky hill. This part of Lisbon is ancient, and is composed of narrow, tortuous streets: it retains the old Moorish appellation of *Alfama*. The churches are numerous, and are nearly all in the same tasteless Italian style; the interiors, overlaid by heavy ornament, contain pictures utterly devoid of merit. Perhaps the one best worth visiting is the *Estrella*, with a dome and two towers, something on the plan of St Paul's at London. The view from the dome is very extensive. The church of St Vincent de Fora, standing in a conspicuous position near the citadel, is considered to be the largest in Lisbon; its dimensions being 222 feet by 82. In an attached chapel, recently built, the coffined corpses of most of the Portuguese monarchs are deposited, and are exhibited to the public on certain days in the year. In the church of St Roque is a chapel, which was constructed at Rome of silver and the richest stones, by order of John V., and which was first erected at Rome, in order that the pope might perform mass in it, previous to its shipment to Lisbon. It is said to have cost upwards of £120,000. Part of the cathedral behind the high altar

is ancient, and deserves inspection. Near the custom-house is a church, formerly a synagogue, with an old and richly-carved portico. At the Carmo are the ruins of a church in the pointed style. It was commenced to be rebuilt after being thrown down by the earthquake, but was not completed. These seem to be the only remains of what we should term Gothic architecture to be found in Lisbon itself; but at Belem there is the church of St Jeronimo, commenced in 1500, on the spot where Vasco de Gama embarked, three years before, on his famous voyage to India. This, and the adjacent cloisters of an extinct monastery, are very interesting.

The museums of Lisbon exist but in name; and the botanical garden at Ajuda is wretchedly managed. The gallery of the Academy of Fine Arts contains only two or three pictures worth notice; and the private collections, of which there are few, are generally poor. The great public library consists, for the most part, of old theological works and ecclesiastical histories, swept out of various suppressed monasteries. The books, uncatalogued and uncared for, are rotting to pieces. They are said to be about 86,000 in number, and with them are kept 8000 MSS., and a collection of 24,000 coins. The Library of the Academy of Sciences, amongst its 50,000 volumes, hardly contains a modern book on any branch of science. The King's Library, at the Necessidades Palace, is said to contain 28,000 volumes; and that at the Ajuda Palace, 20,000 volumes. The Patriarch's Library contains 24,000 volumes. The Portuguese take very little interest in literature, science, or art, and almost everything connected with them is in a neglected state. The national printing-office, however, seems in good hands, though the work done is not of the highest class, or of great extent. This is a government establishment, in imitation of those at Paris and other continental cities. Literary and scientific societies are few in number, and of little importance. The principal one is the Royal Academy of Sciences, founded in 1779; its transactions are scarcely known out of Lisbon, though represented by the Portuguese themselves to be numerous and most important; whilst the voluminous memoirs are said to form an inexhaustible treasury of science. Eight newspapers appear daily in Lisbon, and six weekly, the total circulation of which is thought not to exceed 3500 copies. There are, besides, various fortnightly and monthly publications, five of which are medical, and two religious periodicals. The booksellers' shops are few, and badly stocked.

As the metropolis of the kingdom, Lisbon contains the various offices of the central government, most of which are in the *Praça do Commercio*. Here, also, meets the municipal chamber, a body consisting of a president and eleven members, called *vereadores*, whose duties are to superintend the lighting, paving, and cleansing of the city, to establish regulations for safety against fire, and for the proper distribution of the water brought by the aqueduct. The two chambers of parliament hold their sittings in a huge building, formerly the monastery of St Bento. A telegraphic wire has been lately put up, to establish electric communication between the office of the minister of public works, the chambers of parliament, and the royal palaces of Necessidades and Cintra. The supreme courts of justice sit in Lisbon, as well as various minor tribunals. Here are also naval and military arsenals. Attached to the naval arsenal is a school, an observatory, and a hydrographical office. There are barracks in various parts of the town for the accommodation of the soldiery. The armed municipal guard consists of 160 cavalry, and 1170 infantry. The aqueduct spoken of above was erected more than 100 years ago, in the reign of John V. It brings water from certain springs, situate about 7 miles to the N.W. of Lisbon, and crosses, in its course, 127 arches of excellent workmanship, 35 of which form the bridge across the valley

Lisbon.

Lisbon. of Alcantara; the extreme height here being 263 feet. There is a tradition, that only one stone was shaken from the parapet of this bridge at the great earthquake, the aqueduct beyond being wholly uninjured. Through its whole length, the aqueduct is arched overhead, at a height of 8 feet above the floor; and there is a foot-path between the water-courses. On approaching Lisbon it is divided into three branches, the middle one of which terminates at a large square tank, 31 feet deep, the vaulted roof of which is supported on thick pillars. There is a broad walk round the tank, and from the flat roof an extensive view is obtained. On leaving the tank, the water is conducted along two channels to different points of the city.

There are several cemeteries near Lisbon, and the practice of interring in churches has for some years been abandoned. The monthly mortality may be estimated at 600. In the cemetery set apart for the English lies our novelist Fielding, who died at Lisbon in 1754. A large marble sarcophagus, bearing a long Latin inscription, covers his remains. The British residents maintain a chaplain, who performs service weekly in an adjacent chapel. The largest of the hospitals is that of St José, where there is an average number of 900 patients. The great lunatic asylum of Rilhafoles usually contains nearly 400 patients. At the founding hospital more than 2000 infants are annually received. There is a very interesting establishment at Belem, called the Casa Pia, where 900 children of both sexes are clothed, maintained, and educated gratuitously.

Ecclesiastically, Lisbon is a patriarchate, the holder of the dignity being at the head of the clergy, and president of the Chamber of Peers.

Lisbon is the largest port in the kingdom. The custom-house is a spacious and very substantial building, worthy of any capital in Europe. As the merchants are allowed to deposit their goods here for a year (two years for Brazilian produce) free of duty, it saves them the expense of private warehouses; and this arrangement offers great advantages to the trading community, which are generally taken advantage of. In 1851 there entered the port of Lisbon 1908 vessels, having an aggregate tonnage of 198,893. The produce of the Lisbon custom-house, after paying its expenses, amounted, in 1851, to L.477,700; that of the municipal custom-house, where a duty similar to the French *octroi* duty is levied upon all articles of consumption entering the city, to L.209,400. A large body of foreigners dwell here in the character of merchants, nearly fifty of whom are British firms. Brazil and Great Britain are the two countries with which the most active commerce is carried on; tropical produce being imported from one, and manufactures from the other,—wine and oil being sent to both in return. Lisbon has one joint-stock bank, called the Bank of Portugal, a few fire and life insurance offices, and some joint-stock companies, the chief of which are,—the Company for Cultivating the Productive Islands in the Tagus, with a capital of L.45,000; the Newfoundland Fishery Company, with a capital of L.11,000; the Lisbon Spinning and Weaving Company, with a capital of L.20,000; and the Gas Company, with a capital of L.10,000. Manufactures are carried on only to a small extent at Lisbon, and machinery is little employed. There are a few steam-mills for grinding corn, expressing oil, and sawing wood. There is also a large sugar-refinery, as well as some woollen, cotton, and silk mills, but none of these will bear comparison with British establishments of the same kind. All the coal employed at these places is imported from England. In the immediate neighbourhood of Lisbon stands the tobacco manufactory, belonging to a company which has a monopoly from government for the whole kingdom, paying L.294,000 annually for the privilege. About 1600 persons are employed here, and three millions of lbs. of tobacco are manufactured in the year. The machinery is set in motion

by two steam-engines, and, like most of the machinery at Lisbon, is of British make. Several small steamers ply on the river, and connect Lisbon with the neighbouring towns on its banks. There is communication three times a-month with Southampton by means of the Oriental and Peninsular Company's steamers, which call here on their way to the Mediterranean. The steam-packets of a British-Brazilian Company call here monthly, on their way to and from Rio Janeiro; and the Portuguese have also a line of their own to Brazil. There is also steam communication two or three times a-month with Liverpool. Various steamers connect Lisbon with Oporto, Setubal, and the towns of the Algarve. A monthly steamer to the Azores has been projected. As to railways, Portugal does not yet possess one; but a line is in progress from Lisbon to Santarem, a town 44 miles distant, and a short line to Cintra, 17 miles in length, has been projected. A company has been formed to make a line from a point on the opposite bank of the Tagus towards Badajoz, in Spain. Lisbon is tolerably well supplied with flesh-meat, fish, and country produce. A large quantity of excellent fruit is brought into the city for sale during the season. A few lines of omnibuses connect Lisbon with the suburbs and neighbouring villages. These are usually drawn by mules, and are very inconvenient. The same remark may be made of the old-fashioned, rickety carriages which stand for hire in various parts of the city. Some of the private carriages are neat, but small. A heavy duty, amounting almost to a prohibition, is levied on all foreign-made carriages; and hence the Portuguese are obliged to content themselves with vehicles of an inferior class.

The British nation has a minister at the court of Lisbon: he receives a salary of L.4000 per annum, the consul L.600, and the vice-consul L.300.

The climate of Lisbon may be considered healthy: the winter is very mild, frost and snow being rare. In summer the heat is great, and all who have the means betake themselves during the hot months to Cintra, or to some part of the neighbouring sea-coast, where they may have the benefit of a cooler atmosphere. According to the observations of Franzini, extending over twenty years, the mean temperature of Lisbon is 61° Fahr., and the mean fall of rain for sixteen years was 22.9 inches; the mean height of the barometer (corrected to the temperature of 63° Fahr.), at an altitude of 285 feet above the sea, was 30.034 inches. The observations for sixteen years give, as the mean temperature of the seasons,—Winter, 52°; Spring, 60°.5; Summer, 71°.3; Autumn, 59°.5 Fahr. It will give some idea of the fluctuations of the climate to note, that, during the year 1845–55 (an exceptional year), the maximum temperature was 96° 60, and the lowest 31° 64 Fahr., when there was hoar-frost. The prevalent winds, and the number of days on which they blew on the average of sixteen years, were, according to Franzini,—N., 144 days; N.W., 123; S.W., 138. A meteorological observatory has been lately established at the Polytechnic School, which appears to be under good management.

Like London and Paris, Lisbon stands in a basin of the tertiary formation. The upper beds of this basin consist of loose sand and gravel, destitute of organic remains, and not rising to a greater height than 150 feet above the sea. Below these is a series of beds called, by Mr D. Sharpe, the Almada beds, composed of yellow sand, calcareous sandstone, and blue clay, rich in marine remains. It is upon these beds that the greater part of Lisbon stands. Some of them are well exhibited in the cliffs on the S. side of the Tagus, and others have been laid open by the railway cuttings on the N. bank to the E. of the city. They appear to belong to the older Miocene, and have no equivalents in Britain. Mr James Smith ranks them as older than the Touraine beds, and as nearly of the same age as those of Bordeaux and Dax. The total thickness of the

Lisburn. Almada beds, as far as they are disclosed, may be between 400 and 500 feet. Upwards of 150 species of fossils have been obtained from these beds, of which 124 have been determined, and 20 ascertained to be new and peculiar. About 28 per cent. are of recent species. Next comes a tertiary conglomerate, destitute of organic remains, having in one section a thickness of 200 feet. The tertiary deposits cover altogether an area of between 2000 and 3000 square miles. They are separated, near Lisbon, from rocks of the secondary epoch by an immense mass of basalt, which overflowed the secondary formations before the deposition of any of the tertiary strata, and contributed by its degradation to form the conglomerate just mentioned. The principal deposit of the basalt has an extreme length of 20 miles, with a greatly varying width. The uppermost of the secondary deposits is a formation, named by Mr D. Sharpe the *Hippurite limestone*, and classed by him as the equivalent of the chalk of Northern Europe. The narrow valley of Alcantara, in the immediate neighbourhood of Lisbon, has been excavated in this deposit; and here there are extensive quarries, where abundance of fossils may be collected. Thirty-four species have been detected, of which 55 per cent. are new. They are principally *Lamellibranchiata*, *Gasteropoda*, and *Radiata*, without any *Cephalopoda* or *Brachiopoda*. This formation, which has a total thickness of upwards of 500 feet, was probably deposited in a quiet sea of moderate depth. Between the Hippurite limestone and the granite range of Cintra, the highest part of which is about 2000 feet, there have been observed four deposits, for information as to which we must refer to Mr D. Sharpe's *Memoirs*. In speaking of the Almada formation, a bed of blue clay was mentioned. Mr Sharpe discovered, by careful investigation, that the greatest force of the earthquake of 1755 was expended upon the area of this clay, and that not one of the buildings standing upon it escaped. Those upon the slopes of the hills immediately above the clay suffered very severely, and the whole of the tertiary strata were more or less affected by the shocks; whilst none of the buildings erected upon the Hippurite limestone or the basalt suffered any injury whatever; the line at which the earthquake ceased to be destructive corresponding exactly with the boundary of the tertiary beds.

LISBURN, a market-town and parliamentary borough of Ireland, is situate on the Lagan, partly in Upper Castle-reagh barony, county of Down, and partly in Upper Maserene barony, county of Antrim, 8 miles S.S.W. from Belfast by the Ulster Railway. Having been destroyed by fire in 1707, the town has a modern aspect. It consists chiefly of a long irregular street of houses, well built, and roofed with slate. It is paved, and lighted with gas. At the end of the main street stands the cathedral for the united diocese of Down and Connor,—a picturesque edifice, surmounted by an octagonal spire, of date 1807, and containing the tomb and monument of its bishop, Jeremy Taylor, who died at Lisburn in 1667. There are also a chapel of ease, a Presbyterian church, a Roman Catholic chapel, and meeting-houses for Methodists and Quakers. Besides several schools, it has an institution endowed by John Hancock, for the maintenance and education of forty Quaker children, an infirmary for the county of Antrim, a union workhouse, and a linen hall. The gardens of the old ruined castle are open to the public. Its manufactures are,—linen thread, damasks, muslins, and diapers, and flax-spinning and bleaching are extensively carried on. Great facilities for trade are afforded by its position on the railway and on the river, and its weekly markets on Tuesday are well supplied with manufactured and agricultural produce. Its fairs are held on the 21st of July and the 5th of October. It is the seat of courts for Kilultagh Manor, courts leet, and petty sessions. The borough returns a member to parliament, and gives the title of Viscount to the family of

Vaughan. Lisburn was founded by Viscount Conway, in 1627, beside the castle which his ancestor Sir Fulk Conway had erected in 1610, and was first inhabited by English and Welsh settlers. In 1641 it was laid in ashes by the Irish insurgents. Huguenot families, fleeing thither after the revocation of the Edict of Nantes, imported the linen manufacture. It was again burnt in 1707, but rapidly resumed its prosperity, and is now in a flourishing condition. Pop. (1851) 6569.

LISIEUX (anc. *Noviomagus*, or *Lexovium*), a town of France, capital of a cognominal arrondissement in the department of Calvados, on the right bank of the Touques, 27 miles E. from Caen. It stands in a beautiful valley, and is surrounded by villas and gardens. Its streets, with the exception of the principal one, which forms part of the road between Caen and Evreux, are narrow and winding, and the houses, which are high and antiquated, are built of wood. Its finest buildings are the cathedral, a Gothic structure of the twelfth century, which contains a chapel dedicated to the Virgin (built by Pierre Cauchon, Bishop of Lisieux, whose memory is stained by the part he took in the execution of Joan of Arc), the bishop's palace, a handsome edifice, surrounded by fine gardens, and the theatre. The town contains a communal college, and an ecclesiastical seminary. It has tribunals of primary jurisdiction and of commerce; manufactures of woollen cloth, flannels, cotton and linen yarn; and bleachfields, tanyards, paper and fulling mills, and dyeworks. There is also a considerable trade in fruit, corn, hemp, cider, and flax, which is facilitated by the river being navigable at high water from Lisieux to its mouth. So early as the fourth century, Lisieux was attacked, and almost completely destroyed by the Saxons. The Normans pillaged it in the eighth century, and retained it for a considerable time. It has since been frequently besieged and captured, and was last taken by Henri Quatre in 1588. The fortress was formerly one of great consequence, but the ramparts have been changed into elegant promenades. Pop. (1851) 11,428.

LISKEARD, a parliamentary and municipal borough of England, county of Cornwall, on the Liskeard and Looe Canal and Cornwall Railroad, 16 miles W. by N. of Plymouth. It is built partly on rocky hills, and partly in a hollow; the streets are narrow and irregular, and the houses have a mean appearance. Some handsome buildings have, however, recently been erected in the immediate vicinity. The town-hall, built in the beginning of the eighteenth century, is large and handsome, supported on granite columns. The parish church is a fine Gothic edifice of the fifteenth century, with a tower of more recent date at the west end. The Methodists, Independents, Baptists, and other denominations, have also places of worship here. There are also a grammar and other schools, a mechanics' institution, and a mutual improvement society. The manufactures of Liskeard are few and unimportant, the inhabitants being chiefly dependent on the agricultural and mineral produce of the neighbourhood. Serges and leather are, however, manufactured here. The municipal affairs of the town are intrusted to a mayor, four aldermen, and twelve councillors; and it returns one member to parliament. Pop. (1851) municipal borough, 4386; parliamentary borough, 6204.

LISLE, JOSEPH NICHOLAS DE, an eminent astronomer and geographer, was born at Paris in 1688. His education was commenced under his father, and completed at Mazarin College. An eclipse of the sun in 1706 discovered his taste for mathematics, and to the mathematical sciences he began thenceforth to apply himself. He was appointed engineer at Martinico in 1707; and, in 1709, when he was the correspondent of some of the ablest astronomers in Europe, he had constructed a very accurate quadrant for his own use. He received, in 1715, the grant of a pension of

Lismore
||
Liſſa.

600 livres, but not until pecuniary difficulties had degraded him into an astrologer in the pay of the regent. In that same year he calculated tables of the moon according to the Newtonian theory. Being elected a member of the Academy of Sciences in 1714, he delivered before that body, in 1723, a memoir on the transits of Mercury. In the ensuing year he visited England, and, through Halley and Newton, was elected a member of the Royal Society. A similar honour was afterwards conferred upon him by every literary society in Europe. In 1726 he accepted an invitation from Catherine I. to the chair of astronomy in the Imperial Academy of Sciences at St Petersburg. Travelling into Siberia, in 1740, to observe the transit of Mercury over the sun's disc, he was disappointed in his main object by the cloudiness of the atmosphere, but collected much valuable information on the geography of that country. With the aid of his brother Louis, he constructed a map of Russia; and was engaged at intervals for forty years in meteorological observations. After a stay of twenty-one years in Russia, he returned to Paris, and was elected professor of mathematics in the Royal College, where Lalande and Messier were his pupils. Previous to the transit of Mercury over the sun in 1753, he published a map of the world, representing the effect of that planet's parallaxes in different countries. In 1754 he was appointed by the King of France astronomical geographer to the marine. His last work was an account of the comet of 1758, inserted in the *Memoirs of the Academy*. About the same year he withdrew to the Abbey of St Geneviève, where he died of apoplexy, 11th September 1768. Besides his papers, the principal of which have been mentioned, De Lisle wrote a *History of Astronomy*, 2 vols. 4to, 1738.

LISMORE, an ancient town of Ireland, county of Waterford, on the right bank of the Blackwater, 30 miles N.E. by E. of Cork, and communicating with Youghal by canal and the Blackwater. It stands on an elevation overlooking the river, having on the E. the cathedral, an elegant building with a tower and spire, and on a rocky precipice on the W. the massive old castle. The Blackwater is here crossed by a fine bridge, the centre arch of which has a span of 100 feet. Its chief buildings, besides the above-named, are,—a Roman Catholic chapel, a Presbyterian place of worship, a classical and other schools, a fever hospital, and several alms-houses in behalf of aged Protestant soldiers. Trade is here confined to the agricultural produce of the district, and slates from neighbouring quarries. Lismore is said to have originated from a monastery founded here by St Carthagh in the seventh century. Two centuries later it was several times pillaged by the Danes. In the thirteenth century King John of England founded the castle which, with the town, suffered much during the rebellion of 1641. From that time the town long continued in a state of decay, until it became the property of the Devonshire family, when great improvements were made. The castle is now in complete repair. Pop. (1851) 2340.

LISMORE (Gaelic, *Leosmore*, "The Great Garden"), an island off the W. coast of Scotland, in the county of Argyll, is situate at the mouth of Loch Linnhe, about 7 miles N.N.W. from Oban. Its greatest length is about 10 miles, its average breadth $1\frac{1}{2}$ miles, and its area about 8000 acres. The greater part of the island is under cultivation, and the remainder, though rocky, is covered with a rich green sward, variegated by small clumps of trees. Herring-fishing is carried on by the inhabitants; and limestone is exported. In ancient times the bishops of Argyll inhabited the Castle of Lismore, now in ruins, and were on that account sometimes styled *Episcopi Lismorienses*. There are also the remains of the small Cathedral of St Moluac, the chancel of which is used as a parish church. Pop. (1851) of the united parishes of Lismore and Appin, 4097.

LISSA (Pol. *Leszno*), a town of Prussia, in the pro-

Liſſa
||
Lithgow.

vince of Posen, and 42 miles S.S.W. from the town of that name. Its chief buildings are several churches, a Protestant gymnasium, a synagogue, and a castle. There are extensive manufactories of woollen and linen cloths, leather, tobacco, and chicory. It has a small trade in wine. Pop. (1849) 9635.

LISSA (ancient *Issa*), an island in the Adriatic, off the Dalmatian coast, about 10 miles in length by 5 miles broad, in N. Lat. 43. 5., E. Long. 16. 10. Its shores are generally steep and rocky, and it is only accessible at a few bays. The soil is barren; wine and anchovies form the chief products. Issa was long known to the ancients, and is said by Scylax to have been peopled at an early period by Greeks. During the ascendancy of Rome, the inhabitants had the privileges of Roman citizens, and often assisted that power in its maritime expeditions. In modern times it is famous for the victory gained by the British under Sir W. Hoste over a French squadron, in 1811, after which it was occupied for some time by British troops. The chief town and seaport is San Giorgio, or Liſſa, situate on the N.E. shore, with a pop. of 2800. Pop. of island, 5200.

LISTER, THOMAS HENRY, a novelist, the only son of Thomas Lister, Esq. of Armitage Park, was born in 1801. He produced three novels,—*Granby* in 1826, *Herbert Lacy* in 1827, and *Arlington* in 1832; all descriptive of the manners of the higher classes, of which the author was a member. Without displaying any originality or much skill in the management of a plot, these works are marked by shrewd reflection, a faultless taste both in thought and diction, and a faithful painting of fashionable life. In 1838 Lister published *The Life and Administration of the Earl of Clarendon*, which is now considered a standard biography. Previous to his death, in June 1842, he held the office of registrar-general.

LISTOWEL, a market-town of Ireland, county of Kerry, on the right bank of the River Feale, about 16 miles N.N.E. from Tralee. The town, which has of late years been much improved, consists of one main street, with several small streets diverging from it. There is also a spacious square containing the ancient dilapidated castle, and the parish church. The other principal buildings are,—a fine bridge of five arches spanning the river, an hospital, several schools, a dispensary, and a bridewell. Listowel Castle was the last fortress that held out for Lord Kerry against Queen Elizabeth, and was taken by Sir Charles Wilmot in 1600. Pop. (1851) 3527.

LITHGOW, WILLIAM, a noted traveller, was born in the parish of Lanark in 1583. Early imbued with a propensity for roaming, when he attained to manhood, he set out on a walking tour through the Netherlands, Germany, and Bohemia, trusting probably to benevolence and to his own good fortune to defray the expenses of his journey. He then repaired to Paris, and after remaining there for ten months, proceeded in 1609 to Rome, and afterwards to Naples, trudging along on foot, and refusing on principle the help of any vehicle that passed him on the way. In this manner he wandered through Greece and Asia; and having escaped numberless dangers from robbers, and hardships from exposure to inclement weather, passed over land to Egypt, where three of his fellow-travellers died, and left him their property. He returned to England by Sicily and Paris. Another tour which he made lay through Morocco, Algiers, Tunis, Tripoli, Hungary, Germany, and Poland. On his arrival in London he became an object of interest, and had frequent audiences of James I. Furnished with commendatory letters from the king to all kings, princes, dukes, he sailed to France in 1619, and travelled through Portugal and Spain to Malaga. There he was apprehended as a spy, and after suffering the most horrible manglings and lacerations, first in the prison, and subsequently in the Inqui-

Litho-
graphy.

sition, he was liberated in 1621, and brought to England emaciated almost to death. On recovering his health, he made several futile attempts to gain redress, and, among others, inflicted corporeal chastisement, in the presence-chamber, upon Gondomar the Spanish ambassador. For this

offence he was lodged in the Marshalsea for nine months. He afterwards went to Scotland, and died in his native parish in 1640. The first edition of his *Travels* appeared in London in 1614; the latest in 1814. He also published in 1637 an account of the siege of Buda.

LITHOGRAPHY.

THE invention of lithography is attributed to Alois Senefelder, whose attention was accidentally directed to the effect of a greasy ink on calcareous stone. This effect was the basis on which, after many trials and failures, he built the whole art; for his work on lithography, published about 1817, although containing some antiquated and even absurd notions of the practical operations, comprises a correct skeleton of the entire system of the present day.

Alois Senefelder was born at Prague on the 6th of November 1771. His father, who was an actor in Munich, gave him a tolerable education. When grown up, he was at first undecided whether to become an actor, an author, a musician, or a soldier; but being reduced to great hardship and misery, he resolved to endeavour to support himself as a composer of music. Unable, however, to pay for the engraving of his compositions, he resolved to engrave them himself. Finding this more expensive and difficult than he imagined, he tried, for the sake of economy, to practise with greasy ink on copper, to etch this afterwards with acid in relief, and to print with the common type printing-press. At this period his mother happening to ask him to keep a note of some account, he jotted it down with his greasy ink on a Kelheim slab. Next day it struck him that he might etch such lines with acid in relief, and adopt the slab as a cheaper material for his own purposes than copper. From this beginning, Senefelder gradually discovered the whole process of lithographic or stone-printing.

His first work printed from stone, in 1796, was a piece of music. In 1800 he obtained a patent in Bavaria, and most of the German states. In 1802 he obtained a patent in Vienna, and commenced there a lithographic establishment, but without much success. M. André of Offenbach, the well-known music publisher, became his partner, and opened establishments in London and Paris, but also with little success. The great secrecy and jealousy with which the manipulation of lithography was guarded, prevented its progress; and it was not until the year 1837 that the excessively complicated manipulations became so simplified as to induce scientific men and artists to lend their aid in its development. Since then, rapid advances have been made in Britain, Germany, France, and America; and its beauty and utility as an art are now fully established.

For many years Senefelder was director of the government lithographic office, and in later years the King of Bavaria settled on him a handsome pension for life. He died at Munich in 1834, after having seen his invention brought to comparative perfection.

The principles on which lithography depends are the following:—1st, The adhesion of an encaustic composition to a peculiar kind of limestone; 2d, The power acquired by the parts covered with this greasy composition of receiving printing-ink, which is a compound of carbon and oil; 3d, The power which we possess of preventing the adhesion of the ink by the interposition of a film of water; and, 4th, The power of again removing the ink from the greased portions by simply pressing an absorbent paper into close contact.

Lithographic stones are found in different parts of the world, but nowhere so perfect as in the immense quarries of Solenhofen, near Pappenheim, on the Danube, in

Bavaria. They vary in colour from a pale yellowish-white, to a light buff, reddish, grayish, bluish, and even greenish colour. The fracture is perfectly conchoidal. The beds commence with layers as thin as paper, but the strata become thicker and thicker, until they form slabs or slates of considerable size. They are, until exposed to the air, tolerably soft, and can easily be worked by the quarrymen. Between these layers very beautiful petrifications are found, of which there is a very complete and interesting collection at the Museum in Munich. The slabs were formerly used in Bavaria and elsewhere for the floors of houses and mosques, and were arranged in geometric patterns, like inlaid tiles. In France, useful lithographic stones have been found in the Department de l'Indre; in England, at Corston, near Bath, and at Stony Stratford; and, more recently, in Canada, the West Indies, and Silesia, but all rather inferior to the Solenhofen stone in character. This calcareo-argillaceous stone resembles the liassic limestone,—occurring in layers, as the lias formation does,—but it does not belong to the same geological period, being of a more recent formation.

The stones used for executing writings or drawings with the pen and brush, engraving and etching, autography, and transfers from copper and steel, are first ground between two stones covered with fine sand and water. The uppermost stone is kept moving circularly; water is occasionally added, until the sand between has been completely powdered, resembling a slimy, creamy mass. The sand requires to be renewed until a perfect level is obtained. When stones are ground which have been already in use, this operation has to be continued until all traces of the former work have been thoroughly removed. Every particle of sand is now washed off with water; they are then polished with pumice-stone, and lastly with Water of Ayr stone.

The stones, which must be hard, for chalking, tinting, litho-tinting, and photo-lithography, require to be *grained*. After being ground in the manner already described, and then thoroughly washed, a finely-sifted silicious sand, or finely-ground glass, is put with some water between the two stones; and the upper one is made to revolve in short regular sweeps over every portion of the lower stone. This process must be continued for about ten or fifteen minutes, until a *grain* of the required fineness shall have been produced, and from time to time a few drops of water must be added to prevent the sand from becoming too adhesive, and thus *flattening* the grain. Great care and skill are necessary in nicely adjusting this process, so as to produce a grain either fine, sharp, or rough, according as it is intended for a sketch, for a highly-finished drawing, or for tinting. When grained as required, the stone is thoroughly cleansed with water, and left to dry.

The ink used for drawings on stone is composed of old lard, white soap, white wax, mastic, shell-lac, Venetian turpentine, carbonate of soda, and powdered Paris black.

Crayons are made of white wax, old hard white soap, tallow, a little shell-lac, and powdered Paris black. Some add more or less Brunswick black, so as to give a firmer point to the chalk. Lithographers vary in their modes of preparing writing-inks and chalks. White wax, however, together with soap and Paris black, will enable any practical litho-

Litho-
graphy.

grapher to make a good ink and a good chalk. The method of mixing the different ingredients is by no means uniform. Some put into an iron or copper saucepan, the wax and half of the soap, which is put upon a good fire and stirred until ignition takes place; under the action of this stronger heat, the shell-lac is added, and melted into the mass. The vessel is then closed, and removed from the fire; after some time, the other half of the soap, and the other ingredients, are melted in over a slow fire. The powdered Paris black, together with the Venetian turpentine—if it be used at all—are then added to the mixture. While still hot, the composition is poured into brass moulds. Some, without setting fire to the mixture, make equally serviceable writing-inks and crayons. For harder and softer chalks a difference must be made in proportioning the ingredients. For soft chalk, for example, more tallow is required, and the shell-lac is either omitted, or much diminished in quantity. The ink used for writing on *transfer* paper requires no shell-lac, and, as a consequence, fire is not applied to the mixture.

Drawing and writing on the stone is accomplished by brushes of the finest camel-hair and steel pens.

After the drawing has been traced on the stone, of course in the reverse way, by fixing the tracing paper with the drawn lines next to the surface of the stone, the artist applies himself to his work with pen or brush, and scraper. The latter instrument is of different forms, and chiefly used for corrections; for example, when the artist finds some portion of the shading too strong, he crosses the lines with the scraper, just as the wood-engraver would do in similar circumstances; or a solid portion is filled in, and the scraper is used to bring out the effect in white lines. Or a portion may be taken out altogether, either by means of that instrument, or by oil of turpentine. A tooth-brush is sometimes used advantageously to give the whole drawing, or part of it, the effect of chalk. This is done by slightly warming the stone, and then pressing the tooth-brush, which is only slightly saturated with ink, against the blade of a table-knife, so as to spread a fine spray of dots, varying in size according to the strength used in pressing the brush against the knife. The effect of this under a practised hand is exceedingly pleasing. These imitations of chalk drawing have this advantage, that they admit of being printed by an ordinary printer, that they yield more copies per day than the chalk drawings, that they can be printed on any paper, and can easily be transferred to another stone.

The *tracing of chalk drawings* is done in the same manner as those with the pen or brush. Considerable practice is required in order to produce highly finished chalk drawings on the stone.

Great improvements have resulted from the practice of treating lithographic chalk drawings like paintings, with the systematic design of bringing out the chief effect, instead of copying simply the various details. This has been much facilitated in France and Germany by the use of paper, leather, and cork stumps, which catch up the chalk, pounded on a piece of grained stone slightly heated, and over which they are frequently moved. If the artist will take the trouble to try previously the various effects of texture which the stumps give, when worked gently, and with varying degrees of firmness, on the cold, as well as on slightly and well heated stones, he will be astonished at the variety of the textures which the impression will exhibit when finished with the crayon and scraper. This is well shown in the beautifully lithographed landscapes by Calame of Geneva, the works of Sabatier, Mouil-leron, Le Roux, and others of Paris, Munich, and Berlin. These stumped drawings require great judgment when being etched; but, in the hands of a careful printer, will give a larger number of impressions than ordinary chalk drawings.
